- [Using this web site](#)
- [Contents page](#)

*Cuckoo was moved from the amber to the red list of UK Birds of Conservation Concern in 2009, in recognition of its continuing long-term population decline*

## Using this web site

This web site is a one-stop shop for information about the population status of our common terrestrial birds. It is based on data gathered by many thousands of volunteers who contribute to BTO-led surveys. With one web page per species, users can quickly find all the key information about trends in population size and breeding performance over the period 1966–2008, as measured by BTO monitoring schemes.

The [summary of key findings](#) provides a brief overview of our main findings this year. For each species, we provide:

- General information concerning species' conservation listings and UK population sizes
- A brief summary of observed changes in the size of the population and information concerning the possible causes of these changes
- A series of graphs and tables showing the trends and changes in population size and breeding performance over the past 40 years
- Trends calculated from BTO/JNCC/RSPB Breeding Bird Survey (BBS) data, not only for the UK as a whole but also for each of its constituent countries (England, Scotland, Wales and Northern Ireland)
- Alerts that highlight population declines in any census scheme of greater than 25% or greater than 50% that have occurred over the past 5 years, 10 years, 25 years and the maximum period available (usually 40 years).

Other pages provide details of the field and analytical [methods](#) that were used to produce the results for each species and of the methods used to identify [alerts](#). We [discuss](#) overall patterns of trends in abundance and breeding success, and compare the latest trend information and alerts with the *Birds of*

*Conservation Concern* list ([Eaton et al. 2009](#)). Four [appendices](#) list alerts and population changes by scheme, and there is also a facility to select and display your own [tables of population change](#). A detailed [references](#) section lists more than 300 of the most relevant recent publications, with onward links to abstracts or full text where available, and is a valuable key to recent scientific work by BTO and other researchers.

You can navigate your way around the site using links from the [contents page](#), from the [species index](#), and between sections. Alternatively, use the drop-down menus accessible from the menu bar at the top of each page. 'Species quick links', on the right-hand side of the menu bar, provides a drop-down list (in taxonomic order) with quick access to the species accounts.

The website covers the majority of British breeding birds, 115 species in total, but excludes (with a few exceptions) colonial seabirds, which are well covered by the JNCC's [Seabird Monitoring Programme](#) ([Mavor et al. 2008](#)), and rare species that are included in the reports of the [Rare Breeding Birds Panel](#) (e.g. [Holling & RBBP 2007b](#), [2008](#), [2009](#), [2010](#)).

We value your comments on this report and particularly any suggestions on how it can be improved.

## Key findings

- **Declining species**
- **Reduced breeding success**
- **New alerts**
- **Increased breeding success**
- **Positive changes**
- **Early breeding**

### Declining species

In the current report, there are 22 species for which the best long-term trends provide alerts to statistically significant population declines of greater than 50%.

These are **Grey Partridge**, **Lapwing**, **Woodcock**, **Redshank**, **Turtle Dove**, **Cuckoo**, **Lesser Spotted Woodpecker**, **Skylark**, **Tree Pipit**, **Yellow Wagtail**, **Whitethroat**, **Willow Warbler**, **Spotted Flycatcher**, **Willow Tit**, **Marsh Tit**, **Starling**, **House Sparrow**, **Tree Sparrow**, **Linnet**, **Lesser Redpoll**, **Yellowhammer** and **Corn Bunting**.

*Tree Sparrows have declined by 97% in England over the last 40 years, despite an improving trend since 1997*

All these rapidly declining species are already red or amber listed on the newly revised Population Status of Birds (**PSoB**, **BoCC3**) list. Despite ostensibly meeting a red-list criterion for population decline, the following species are, for various reasons, listed only as amber: **Woodcock**, **Redshank**, **House Martin**, **Whitethroat** and **Willow Warbler**. For several of the species listed, long-term trend data are available only for England, where BTO has more volunteers to record information. Different long-term trends could be operating in other parts of the UK. **Lesser Redpoll**, **Tree Pipit** and **Woodcock**, in particular, have limited data.

A further nine species trigger lower-level alerts, as a result of statistically significant long-term declines of between 25% and 50% over periods of 25 to 40 years. These are **Common Sandpiper**, **Little Owl**, **Meadow Pipit**, **Grey Wagtail**, **Dipper**, **Dunnock**, **Song Thrush**, **Mistle Thrush**, and **Bullfinch**. All of these species are on the current amber list on account of their population declines, except for **Song Thrush**, which remains red listed, **Dipper**, which remains on the green list, and **Little Owl**, which as an introduced species has no conservation listing.

In addition, **Little Grebe** (-35% since 1975), **Curllew** (-29% since 1967) and **Nightingale** (-45% on CES since 1984) have also declined by more than 25%, but raise no alerts because the confidence intervals around their change estimates are too wide.

### Recent alerts and alert changes

We draw special attention to the alert for **Redshank**, which has recently crossed the 50% decline threshold in the 25-year period. This species and **House Martin**, both currently amber listed, may already be candidates for addition to the red list at the next PSoB revision.

*Redshanks have decreased by 56% since 1975 according to WBS/WBBS data and are also strongly declining on BBS sites*

**Grey Wagtail** (-26% since 1975) and **Dipper** (-30% over the same period), also raise alerts here but did not do so in our previous report. Their estimates have been improved by the inclusion of WBBS data for the first time. **Dipper** currently has no conservation listing but may now be a candidate for the amber list.

There are also two species that have moved to a lower category since the previous report. The 40-year change for **Song Thrush** is now marginally below the 50% threshold. **Little Grebe** raised a high alert last year with its decline on waterways, which then measured -59%. Its trend estimate since 1975 is now -35% and, because the confidence interval is wide, this does not raise an alert.

## Positive changes

For eight species that meet red or amber criteria for population decline over the long term – **Little Grebe**, **Lapwing**, **Skylark**, **House Martin**, **Meadow Pipit**, **Mistle Thrush**, **Bullfinch** and **Yellowhammer** – decline has started to level off, or has ceased, during the recent ten-year period.

Seven formerly declining species – **Snipe**, **Grey Wagtail**, **Dunnock**, **Song Thrush**, **Whitethroat**, **Tree Sparrow** and **Reed Bunting** – have shown significant positive trends over the last ten years. Where the earlier decline had been strong or long-lasting, however, as for the red-listed **Tree Sparrow**, population levels remain severely depleted.

The increase in the red-listed **Song Thrush** is particularly encouraging. **Reed Bunting** was also red listed until 2009, but its recent positive trend has allowed it to move to the amber list. Although BBS shows a 35% increase in **Snipe** over the last ten years, much of the former range across lowland Britain remains unoccupied, and moreover increase has ceased again since 2003.

*The introduced non-native Ring-necked Parakeet has been monitored by BTO surveys only since 1994: with an increase of 600% during 1995–2007, it is the fastest-increasing species in this report*

Although not quite matching the 22 species that have at least halved, there are 19 species that have more than doubled over the long term (usually 40 years). These are **Mute Swan**, **Canada Goose**, **Shelduck**, **Mallard**, **Tufted Duck**, **Sparrowhawk**, **Buzzard**, **Stock Dove**, **Woodpigeon**, **Collared Dove**, **Green Woodpecker**, **Great Spotted Woodpecker**, **Wren**, **Reed Warbler**, **Blackcap**, **Great Tit**, **Nuthatch**, **Magpie** and **Carriion Crow**. Heading the list of long-term upward trends is **Buzzard**, which has increased by 444% in the UK over the last 40 years.

Over a shorter period, **Cetti's Warbler** has increased by 280% since 1997. Two further species with only relatively recent coverage are the fastest increasing species of all in this report – **Greylag Goose** (+430% since 1993) and the non-native **Ring-necked Parakeet** (+600% since 1995). These are both introduced

species: the parakeet is non-native and, although **Greylag Goose** is native to the UK, its presence as a breeder over much of Britain is due solely to introductions and restocking.

## Reduced breeding success

*Spotted Flycatchers, in severe population decline, are fledging fewer young*

The current report introduces a new summary figure, Fledglings Per Breeding Attempt (FPBA), representing the mean number of young leaving each nest in a given year. Eight species exhibit negative trends in FPBA over the past 20 years or more, indicating that reproductive output has decreased over time, including four BoCC red-listed species (**Nightjar**, **Spotted Flycatcher**, **Linnet** and **Yellowhammer**), three amber-listed species (**Bullfinch**, **Reed Bunting** and **Dunnock**) and one green-listed species (**Chaffinch**). While productivity of **Nightjar**, **Reed Bunting** and **Linnet** has been falling since the mid 1960s, declines in breeding success of the remaining five species have occurred over the last 15–20 years.

Productivity declines in the migrant **Nightjar** and **Spotted Flycatcher** may be driven by changes in habitat and/or climate on the African wintering grounds or by climate-mediated disjunction with their invertebrate prey species on the breeding grounds. Alternatively, declining insect numbers in the UK may have reduced the amount of food available to both parents and nestlings.

Studies of declining **Linnet**, **Reed Bunting** and **Yellowhammer** populations have identified winter food availability as a key factor, and loss of condition during the winter could depress subsequent breeding success. These species, along with **Dunnock** and **Bullfinch**, may also have suffered from a loss of scrub habitat mediated at least in part by the increasing numbers of deer. **Chaffinch** populations are increasing steadily and it is possible that declines in breeding success may be density dependent, resulting from increased intraspecific competition or range expansion into suboptimal habitats.

CES ringing data indicate that productivity has fallen by more than 20% for 13 of the species monitored by this scheme (**Nightingale**, **Blackbird**, **Song Thrush**, **Garden Warbler**, **Blackcap**, **Sedge Warbler**, **Willow Warbler**, **Blue Tit**, **Great Tit**, **Linnet**, **Lesser Redpoll**, **Goldfinch** and **Reed Bunting**). Declines in FPBA for both **Linnet** and **Reed Bunting** suggest that these trends may be driven by declines in the productivity of individual attempts rather than by changes in the number of breeding attempts or in post-fledging survival rates. Seven species (**Nightingale**, **Song Thrush**, **Sedge Warbler**, **Willow Warbler**, **Linnet**, **Lesser Redpoll** and **Reed Bunting**) have experienced significant population declines, either on CES sites or more widely.

## Increased breeding success

Increasing breeding performance may be helping to drive population expansion of a number of rapidly increasing species: the predatory **Sparrowhawk**, **Buzzard** and **Barn Owl**; the columbids **Collared Dove** and **Stock Dove**; the corvids **Jackdaw**, **Magpie** and **Carrion Crow**; the resident insectivores **Pied Wagtail**, **Grey Wagtail**, **Robin**, **Stonechat**, **Nuthatch**; and the migrant insectivores, **Redstart** and **Reed Warbler**. Six further species (**Skylark**, **Dipper**, **Mistle Thrush**, **Starling**, **House Sparrow** and **Tree Sparrow**) are exhibiting significant increases in productivity as populations decline, which may be due to density dependence.

*Breeding success is improving for Reed Warblers*

## Early breeding

*On average, Pied Flycatchers are now laying 11 days earlier than in 1968*

Data from the Nest Record Scheme provide strong evidence of shifts towards earlier laying in a range of species, linked to climate change. We have now identified 43 species that, on average, are laying between 4 and 30 days earlier than in the mid 1960s. The species involved represent a wide range of taxonomic and ecological groups, including raptors (**Kestrel** – 7 days), waterbirds (**Moorhen** – 5 days), waders (**Oystercatcher** – 5 days), migrant and resident insectivores (**Pied Flycatcher** – 11 days, **Blue Tit** – 10 days), corvids (**Magpie** – 30 days) and resident seed-eaters (**Greenfinch** – 15 days).

For some species these shifts towards earlier laying may be insufficient to track seasonal advances in food availability. Recent research has shown that significantly stronger phenological responses to climate change are displayed at lower than at higher trophic levels, increasing the potential for disjunction and resulting population declines (**Thackeray et al. in press**).

## 1. INTRODUCTION

Since its formation in 1933, BTO has been deeply committed to gathering quantitative information on the bird populations of the UK. Its nationwide network of skilled volunteers, many of whom are long-term contributors to survey schemes, provides the ideal way to monitor the bird populations that are widely distributed across the countryside. BTO data, from such schemes as the [Common Birds Census](#), [Nest Record Scheme](#) and [BTO/JNCC/RSPB Breeding Bird Survey](#), have been increasingly influential in determining nature conservation policy in the UK. The partnership between JNCC and BTO has ensured that these schemes are operated and developed so as to provide high-quality information for nature conservation.

The value of the monitoring work undertaken by the BTO was recognised in the Government's Biodiversity Steering Group report ([Anon. 1995](#)). The BTO's results, particularly those regarding declining farmland species, are highlighted as an example of the way in which broad-scale surveillance techniques can identify important new trends. More generally, the report states that monitoring is essential if the broad aims, specific objectives and precise targets of the Government's Biodiversity Action Plans are to be achieved. It notes that:

- baselines must be established;
- regular and systematic recording must be made, to detect change; and
- the reasons for change should be studied, to inform action.

The BTO's monitoring schemes fulfil a considerable portion of these needs for a wide range of bird species in the UK.

The current system of [alerts](#) derived from the BTO's census and nest record data ensures that conservation bodies are quickly made aware of important demographic changes. Multi-species [indicators](#), making extensive use of BTO census data, track how bird populations are faring generally across the countryside, UK-wide and within specific regions or habitats. These indicators were developed in association with Government and some have been adopted by them as policy drivers. More recently, indicators have been developed on the European scale ([click here](#)).

### 1.2 [The value of combining results from different monitoring schemes](#)

### 1.3 [The aims of this report](#)

---

## 1.1 The BTO's monitoring of breeding birds in the UK

The Integrated Population Monitoring Programme has been developed by the BTO, in partnership with JNCC, to monitor the numbers, breeding performance and survival rates of a wide range of bird species. It has the following specific aims ([Baillie 1990, 1991](#)):

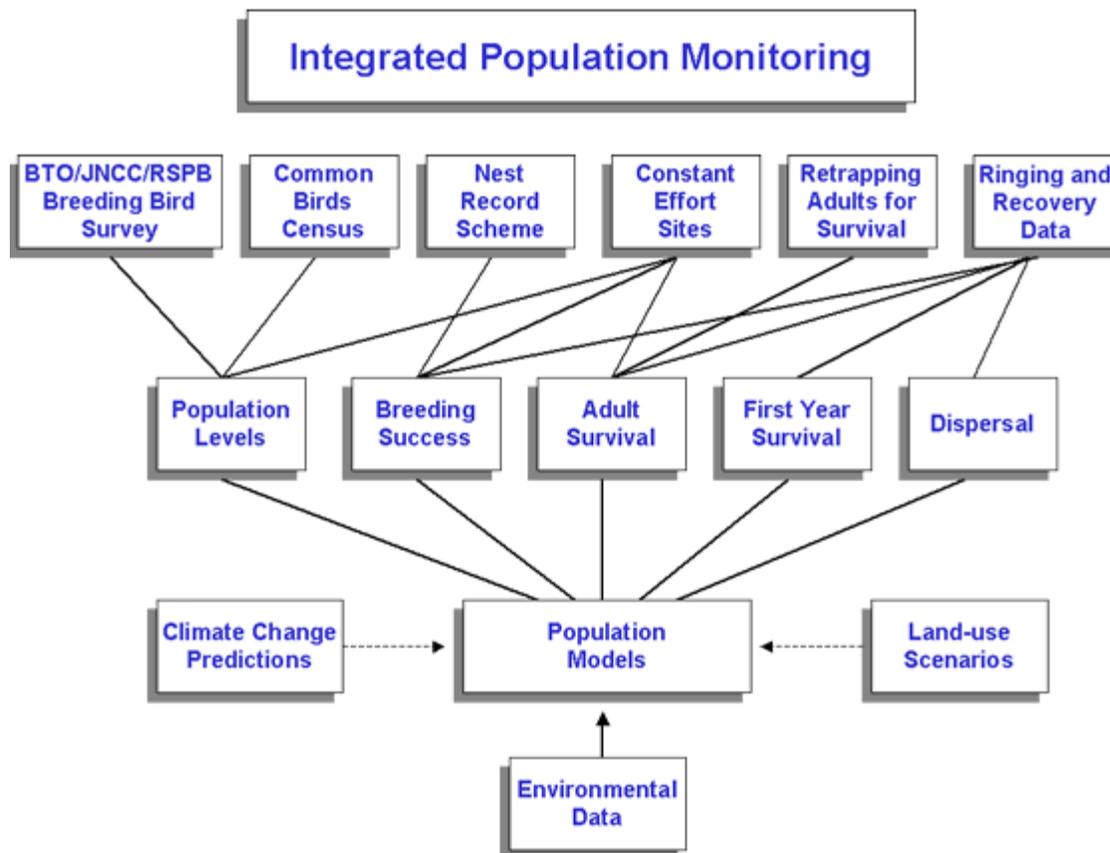

- (a) to establish thresholds that will be used to notify conservation bodies of requirements for further research or conservation action;
- (b) to identify the stage of the life cycle at which demographic changes are taking place;
- (c) to provide data that will assist in identifying the causes of such changes; and
- (d) to distinguish changes in population sizes or demographic rates induced by human activities from those that are due to natural fluctuations.

The programme brings together data from several long-running BTO schemes.

- Changes in numbers of breeding birds are measured by:
  - the [BTO/JNCC/RSPB Breeding Bird Survey \(BBS\)](#) – which began in 1994 and replaced the CBC (below) as the major monitoring scheme for landbirds, after a seven-year overlap. BBS is based on around 3,000 1-km squares, within each of which birdwatchers count and record birds in a standardised manner along a 2-km transect. Because the survey squares are chosen randomly, the results are not biased towards particular habitats or regions. Combined [CBC/BBS](#) indices now provide long-running and ongoing population monitoring for many common birds.
  - the [Common Birds Census \(CBC\)](#) – which ran from 1962 to 2000. This scheme mapped the breeding territories of common birds on 200–300 mainly farmland and woodland plots each year, averaging about 70 and 20 ha respectively.
  - the [Waterways Breeding Bird Survey \(WBBS\)](#) – which began in 1998 and replaced the WBS (below) as the major monitoring scheme for breeding birds along rivers and canals, after a ten-year overlap. It is a transect scheme akin to BBS but with transects running alongside linear waterways. Transects comprise up to ten 500-m sections and cover typically 3–3.5 km of rich habitat. Around 250–300 sites are covered each year. Combined [WBS/WBBS](#) indices now provide long-running and ongoing population monitoring for many common waterside birds.
  - the [Waterways Bird Survey \(WBS\)](#) – which ran from 1974 to 2007. WBS observers mapped the territories of birds along rivers, streams and canals on 80–130 plots each year, each on average 4.5 km long. Around 70 of these sites are now incorporated within WBBS.
  - the [Constant Effort Sites Scheme \(CES\)](#) – which began in 1983 and is based on bird ringing at over 100 sites. The catching effort is kept constant at each site during each year, so that changes in numbers of birds caught will reflect population changes and not variation in catching effort.
  - the [Heronries Census](#) – through which counts of 'apparently occupied nests' have been collected from a high proportion of the UK's heronries every year since 1928.
- Changes in breeding performance are measured by:
  - the [Nest Record Scheme](#) – which began in 1939 and collates standardised information on up to 35,000 individual nesting attempts per year. This allows the measurement of:
    - laying dates
    - clutch sizes
    - brood sizes
    - nesting success during egg and chick stages
    - fledglings per breeding attempt (integrating success across all nesting stages).
  - the [CES](#) (see above) – which provides information on overall productivity for a range of species by measuring the ratio of juveniles to adults caught each year.
- Changes in survival are measured by:
  - the [British and Irish Ringing Scheme](#) – which provides information on the finding circumstances and longevity of ringed birds found dead by members of the public.
  - The [CES](#) also provides information on survival rates, based on the recapture of ringed birds at

constant-effort sites. In future, further information on survival rates will be provided through the [Retrapping Adults for Survival](#) (RAS) scheme.

The ways in which the schemes fit together are shown in the diagram below, which also demonstrates the way in which the BTO aims to combine all this information to understand the mechanisms behind changes in population sizes using population models.

[Next section –1.2 The value of combining results from different monitoring schemes](#)

[Back to Introduction Index](#)

## 1.2 The value of combining results from different monitoring schemes

Monitoring the changes in the size of a population does not in itself provide sufficient information on which to base an effective conservation strategy ([Goss-Custard 1993](#), [Furness & Greenwood 1993](#)). Concurrent monitoring of breeding performance and survival rates is necessary to allow changes in population size to be properly interpreted ([Temple & Wiens 1989](#), [Crick \*et al.\* 2003](#)) and, for long-lived species, can provide early warning of impending conservation problems ([Pienkowski 1991](#)).

Where good long-term data sets for breeding performance and survival are lacking, conservation action might have to be taken without an adequate understanding of the mechanisms involved or might need to wait years for detailed research to be undertaken. For many species, however, BTO already has the necessary data, collected by its volunteers over periods of several decades ([Greenwood 2000](#)).

For a long-lived species, a decline in population may not begin until a long period of low survival or reduced reproductive output has already passed. The classic example is that of the [Peregrine](#), which in the UK suffered from poor breeding performance during the 1940s and 1950s due to sub-lethal DDT contamination. This decreased the capacity of the non-breeding population to buffer the severe mortality of breeding adults that occurred due to cyclodiene poisoning from the mid 1950s onwards ([Ratcliffe 1993](#)). Monitoring of breeding performance gave an early warning of subsequent numerical decline ([Pienkowski 1991](#)). Another example of a decline in breeding performance that presaged population decline is the catastrophic breeding failures of seabirds, particularly Arctic Terns, in Shetland ([Monaghan \*et al.\* 1989, 1992](#), [Walsh \*et al.\* 1995](#), [Mavor \*et al.\* 2003, 2004](#), [Wanless \*et al.\* 2005](#)).

### Farmland birds

During the mid 1980s, the BTO identified rapid declines in the population sizes of several farmland bird species ([O'Connor & Shrubbs 1986](#), [Fuller \*et al.\* 1995](#)). The BTO has since been able to investigate the demographic mechanisms underlying these declines, using its long-term historical data sets ([Siriwardena \*et al.\* 1998a, 2000a](#)).

This investigation, which was Government-funded and undertaken jointly with Oxford University, looked at changes in population size, breeding performance and survival rates of a variety of species in relation to changing farming practice. It showed that species responded to different aspects of the agricultural environment, but that typically these aspects were linked to intensification or regional specialisation. Declines in survival rates were found to be the main factor driving population decline in these species, with the exception of [Linnet](#), for which the main factor appears to have been a decline in nesting success at the egg stage ([Siriwardena \*et al.\* 2000b](#)). The study was therefore able to eliminate some possible causes of change, and identify areas for future research, thus helping conservation bodies to use their scarce resources productively. This work made an important contribution to the wider programme of work on farmland birds undertaken by many research and conservation organisations ([Aebischer \*et al.\* 2000](#), [Vickery \*et al.\* 2004](#)).

This report describes a number of other cases where the combined analysis of BTO data sets has helped to identify the causes of population declines, for example on the pages for [Lapwing](#) ([Peach \*et al.\* 1994](#)), [Song Thrush](#) ([Baillie 1990](#), [Thomson \*et al.\* 1997](#), [Robinson \*et al.\* 2004](#)), [Sedge Warbler](#) ([Peach \*et al.\* 1991](#)), [Willow Warbler](#) ([Peach \*et al.\* 1995a](#)), [Spotted Flycatcher](#) ([Freeman & Crick 2003](#)), [Starling](#) ([Freeman \*et al.\* 2002, 2007b](#)), and [House Sparrow](#) ([Freeman & Crick 2002](#)). A fully integrated approach, estimating trends in numbers and demographic parameters through a single model containing data from various BTO surveys, has been introduced by [Besbeas \*et al.\* \(2002\)](#). More recently, the use of state-space models and Bayesian techniques for integrated monitoring has been pioneered by [Baillie \*et al.\* \(2009\)](#).

### Biodiversity Action Plans

The ability to quickly determine the stage of the life-cycle most heavily involved during population

declines is particularly important for the conservation agencies when considering the plight of species on the lists of conservation concern ([JNCC 1996](#), [Anon. 1995](#), [1998](#)). Analysis of BTO data sets, which has already helped to build these lists, is a key point in several of the UK Government's [Biodiversity Action Plans](#) for rapidly declining species. Once conservation actions have been initiated, the BTO's Integrated Population Monitoring programme has a further function, because the success of these actions will be measured and assessed by continued BTO monitoring.

**[Next section – 1.3 The aims of this report](#)**

**[Back to Introduction Index](#)**

---

[BBWC Home](#) > [Contents](#) > [Introduction](#) > [The aims of this report](#)

## 1.3 The aims of this report

This report is the latest in a series of reports that are used by conservation practitioners as a ready-reference guide to recent changes in status of breeding birds in the UK. By publishing it on the BTO website, we aim to make it available to a much wider audience, especially to BTO members and the general birdwatching public. We hope that it also provides a useful resource for schools, colleges and universities, the media, ecological consultants, decision-makers, local government, and the more general world of industry and commerce. In summary, its aims are:

- 1) To provide, to as wide a readership as possible, a species-by-species overview of the trends in breeding population and reproductive success of birds covered by BTO monitoring schemes since the 1960s, at the UK or UK-country scale.
- 2) To provide warning alerts to JNCC and Country Agencies and to other conservation bodies about worrying declines in population size or reproductive success, with special reference to species on the UK red and amber lists.

This document is the result of the sustained fieldwork of many thousands of the BTO's volunteer supporters. Without their enthusiasm for collecting these hard-won facts, the cause of conservation in the UK would be very much the poorer. The data we present here include information on distributions, from breeding-season and winter atlas projects, and on estimates of the absolute size of breeding populations, which are reported at intervals by the Avian Population Estimates Panel ([Stone \*et al.\* 1997](#), [Baker \*et al.\* 2006](#)). Colonial seabirds, which are well covered by the results of Seabird 2000 ([Mitchell \*et al.\* 2004](#)) and by the JNCC's [Seabird Monitoring Programme \(Mavor \*et al.\* 2008\)](#), and the majority of species covered by the [Rare Breeding Birds Panel \(Holling & RBBP 2007b, 2008, 2009, 2010\)](#), are not included here. Wintering populations of waterfowl are covered by the Wetland Bird Survey annual reports (e.g. [Holt \*et al.\* 2009](#)) and by the WeBS alerts system ([Maclean & Austin 2008](#)).

The main emphasis of this report is on trends in the abundance and demography of individual species. The data on trends in abundance also provide the basis for multi-species [indicators](#) of bird population changes ([Gregory \*et al.\* 2004](#)). The [Wild Bird Indicator](#) has been adopted as one of the UK Government's 15 headline Quality of Life indicators. Furthermore, the related [Farmland Bird Indicator](#) is being used as the basis of the Government's target for farmland bird recovery. This approach is now being extended more widely through a collaboration between EBCC, BirdLife and RSPB to produce [pan-European bird indicators](#).

The report is the latest in a series, begun in 1997, produced under the BTO's partnership with the Joint Nature Conservation Committee (on behalf of Natural England, Scottish Natural Heritage, the Countryside Council for Wales, and the Council for Nature Conservation and the Countryside) as part of its programme of research into nature conservation. Only the first two reports were published as paper reports, with subsequent ones being produced solely as web documents. A complete list of all the previous reports and links to those published online can be found [here](#).

[Section 2 – Methodology](#)

[Back to Introduction Index](#)

---

## 2. METHODOLOGY

Seven monitoring schemes have contributed data to this report. Six provide data on changes in abundance: these are the **Breeding Bird Survey**, **Common Birds Census**, **Waterways Breeding Bird Survey**, **Waterways Bird Survey**, **Heronries Census** and **Constant Effort Sites** ringing scheme. Two schemes, the **Nest Record Scheme** and Constant Effort Sites, provide data on changes in breeding productivity. In addition, information from detailed analyses of the recoveries of ringed birds, from the Ringing Scheme, and on waterbirds from the Wetland Bird Survey, is included where relevant.

The methodologies of the monitoring schemes are described below, including information on fieldwork, data preparation, sampling considerations and the statistical methods used in analysis.

- 2.1 [Breeding Bird Survey](#)
- 2.2 [Common Birds Census](#)
- 2.3 [Combined CBC/BBS trends](#)

## 2.1 Breeding Bird Survey

The BTO/JNCC/RSPB Breeding Bird Survey (BBS) was launched in 1994, following two years of extensive pilot work and earlier desk-based studies. The introduction of the BBS was a move designed to overcome the limitations of the [Common Birds Census](#) (CBC), which had monitored bird populations since 1962. In particular, it improves the geographical representativeness of UK bird monitoring, thus boosting coverage of species and of habitats.

The BBS uses line transects rather than the more intensive territory-mapping method that was used by the CBC. This makes the survey relatively quick to undertake, and has been successful in encouraging a large number of volunteers to take part. The average time observers spend per visit is only around 90 minutes. Sampling units are the 1x1-km squares of the Ordnance Survey national grid, of which there are some 254,000 in the UK. From these we make random selections, by computer, for inclusion in the scheme (see [Square selection](#), below). The BBS requires a relatively large sample of survey squares, and the initial aim was to achieve coverage of about 2,500 squares.

An important aspect of BBS is its coordination through a network of volunteer BBS Regional Organisers. Information and survey forms are distributed first to these organisers, who contact volunteers willing to survey the squares every year. After the field season, forms are returned to BTO headquarters again via the Regional Organisers, but an alternative, on-line method for submission of BBS data was introduced in 2003 is already used by the majority of observers – see the [BBS pages](#) of the main BTO website for details.

Fieldwork involves three visits to each survey square each year. The first is to record details of habitat and to establish or re-check the survey route, while the second and third (termed 'early' and 'late') are to count birds. A survey route is composed of two roughly parallel lines, each 1 km in length, although for practical reasons routes typically deviate somewhat from the ideal. Each of these lines is divided into five sections, making a total of ten 200-m sections, and birds and habitats are recorded within these ten units. The two bird-count visits are made about four weeks apart (ideally in early May and early June), ensuring that late-arriving migrants are recorded. Volunteers record all the birds they see or hear as they walk along their transect routes. Birds are noted in three distance categories (within 25 m, 25–100 m, or more than 100 m on either side of the line, measured at right angles to the transect line), or as in flight. Recording birds within distance bands provides a measure of bird detectability in different habitats and thus allows population densities to be estimated more accurately. The total numbers of each species, excluding juveniles, are recorded in each 200-m transect section and distance category, as well as the timing of the survey and weather conditions.

By 1998, more than 2,300 BBS squares were being surveyed annually, close to the original target of 2,500. Only around a quarter of these plots were covered in 2001, owing to Foot & Mouth Disease access restrictions, but (thanks to our keen observers) the sample recovered immediately to over 2,100 in 2002 and had increased further to 2,254 squares in 2003, 2,526 in 2004, 2,879 in 2005 and 3,295 in 2006. The sample soared to 3,604 in 2007 ([Risely \*et al.\* 2008](#)). Squares are distributed throughout the UK and cover a broad range of habitats, including uplands and urban areas. There are around 100 species that are present on 40 or more BBS squares annually and so can be monitored with good precision at the UK scale ([Joys \*et al.\* 2003](#)), although a few present special difficulties because of their colonial or flocking habit or their wide-ranging behaviour. For most of these 100 species, BBS can also assess annual population changes within [England](#) alone, using data from 30 or more squares, and for about half the species also within [Scotland](#) and [Wales](#) as separate units. Sample sizes in [Northern Ireland](#) currently allow about 25 species to be indexed annually.

### Square selection

Survey squares are chosen randomly using a stratified random sampling approach from within 83 sampling regions. These sampling regions, which in most cases are the standard BTO regions, are the 'strata' (literally layers) of the sample. Survey squares are chosen at random within each region, to a density that varies with the number of BTO members resident there. Regions with larger numbers of

potential volunteers are thereby allotted a larger number of squares, enabling more birdwatchers to become involved in these areas. This does not introduce bias into the results because the analysis takes the differences in regional sampling density into account (see below).

### **Data analysis**

Change measures between years are assessed using a log-linear model with Poisson error terms. For each species and square, counts are summed across all sections and distance bands for each visit ('early' and 'late') and the higher value is used in the model (or the single count if the square was visited only once). Counts are modelled as a function of square and year effects. Each observation is weighted by the number of 1-km squares in each region divided by the number of squares counted in that region, to correct for the differences in sampling density between regions. The upper and lower confidence limits of the changes indicate the certainty that can be attached to each change measure. When the limits are both positive or both negative, we can be 85% confident that a real change has taken place (see [section 2.8.4](#) for details).

Trends are presented as graphs in which annual population indices are shown in blue and their 85% confidence limits in green. A caveat, 'small sample', is provided against the trends for England, Northern Ireland, Wales and Scotland where the mean sample size is between 30 and 40 plots per year. A minimum sample size of 40 plots is required for the UK trends.

[BBWC Home](#) > [Contents](#) > [Methodology](#) > [Common Birds Census](#)

## 2.2 Common Birds Census

The Common Birds Census (CBC), which ran from 1962 to 2000, was the first of the BTO's schemes for monitoring population trends among widespread breeding birds, but has now been superseded for this purpose by [BBS](#).

The CBC was instigated to provide sound information on farmland bird populations in the face of rapid changes in agricultural practice. Although the original emphasis was on farmland, woodland plots were added by 1964. Fieldwork was carried out by a team of 250–300 volunteers. The same observers surveyed the same plots using the same methods year after year. On average, plots were censused for around seven consecutive years but a few dedicated observers surveyed the same sites for more than 30 years. Farmland plots averaged around 70 hectares in extent. Woodland plots were generally smaller, averaging just over 20 hectares. A small number of plots of other habitats, including heathlands and small wetlands, were also surveyed annually, especially before 1985.

A territory-mapping approach was used to estimate the number and positions of territories of each species present on each survey plot during the breeding season. Volunteers visited their survey plots typically eight to ten times between late March and early July and all contacts with birds, either by sight or sound, were plotted on outline maps at a standard scale of 1:2,500. Codes were used to note each bird's species, with sex and age where possible, and also to record activity such as song or nest-building. The registrations were then transferred to species maps and returned to BTO headquarters for analysis. The pattern of registrations on the species maps reveals the numbers of territories for each species. All assessments of territory number were made by trained BTO staff, applying rigorous guidelines, to ensure consistency between estimates across sites and years. Observers also provided maps and other details of the habitat on their plots. This makes it possible to match the distribution of bird territories with habitat features, providing the potential for detailed studies of bird–habitat relationships.

In 1990, the results from the Common Birds Census were brought together in the book *Population Trends in British Breeding Birds* ([Marchant et al. 1990](#)). This landmark publication discussed long-term population trends for the years 1962 to 1988 for 164 species, with CBC or WBS population graphs for around two-thirds of these.

The results from the Common Birds Census (CBC) provided reliable population trends for more than 60 of the UK's commoner breeding species and, through the linking of CBC with BBS, continue to be hugely influential in determining conservation priorities in the UK countryside. The store of detailed maps of almost a million birds' territories, collected through the CBC and maintained by BTO since the early 1960s, is a uniquely valuable resource for investigating the relationships between breeding birds and their environment, over wide temporal and spatial scales.

The weaknesses of the CBC as a monitor of UK bird populations were largely related to the time-consuming nature of both fieldwork and analysis. This inevitably limited the number of volunteers able to participate in the scheme, with the result that areas with few birdwatchers were under-represented. Constrained by the relatively small sample size, CBC concentrated on farmland and woodland habitats. Bird population trends in built-up areas and the uplands were therefore poorly represented. Furthermore, as the plots were chosen by the observers, some may not have been representative of the surrounding countryside and some bias towards bird-rich habitats might be suspected. It is for these reasons that the BBS was introduced in 1994. The two surveys were run in parallel for seven years to allow calibration between the results: for many species, CBC and BBS trends can be linked to form joint CBC/BBS trends that provide ongoing monitoring, continuous since the 1960s ([Freeman et al. 2003](#), [2007a](#); [section 2.3](#) of this report).

### Validation studies

The CBC was the first national breeding bird monitoring scheme of its kind anywhere in the world and its value has been widely recognised internationally. The territory-mapping method adopted by the CBC is acknowledged as the most efficient and practical way of estimating breeding bird numbers in small areas, and has been well validated. Although intensive nest searches may sometimes reveal more birds, a comparison by [Snow \(1965\)](#) concluded that mapping censuses were a good measure of the true breeding population for 70% of species. Experiments to test differences between observers'

abilities to detect birds found that, although there was considerable variation between individual abilities, the observers were consistent from year to year ([O'Connor & Marchant 1981](#)). As the CBC relies on data from plots covered by the same observer in consecutive years, this source of bias has no implications for the CBC's ability to identify population trends. It has also been confirmed that the sample of plots from which CBC results are drawn changed little in composition or character over the years ([Marchant \*et al.\* 1990](#)) and that the results of territory analysis are not affected by changes in analysts, once trained ([O'Connor & Marchant 1981](#)). [Fuller \*et al.\* \(1985\)](#) found that farmland CBC plots were representative of ITE lowland land-classes throughout England (excluding the extreme north and southwest), and closely reflected the agricultural statistics for southern and eastern Britain.

### Data analysis

Population changes are modelled using a generalised additive model (GAM), a type of log-linear regression model that incorporates a smoothing function ([Fewster \*et al.\* 2000](#)). This replaces the Mountford model that employed a six-year moving window ([Mountford 1982, 1985, Peach & Baillie 1994](#)) and was used to produce annual population indices until 1999, but the principles are similar. These models are also very similar to log-linear poisson regression as implemented by program TRIM ([Pannekoek & van Strien 1996](#)). Counts are modelled as the product of site and year effects on the assumption that between-year changes are homogeneous across plots. Smoothing is used to remove short-term fluctuations (e.g. those caused by periods of severe weather or measurement error) and thus reveal the underlying pattern of population change. This is achieved by setting the degrees of freedom to about 0.3 times the number of years in the series. Confidence limits on the indices are estimated by bootstrapping (a resampling method; [Manly 1991](#)) and thus do not make any assumptions about the underlying distribution of counts.

Indices are plotted as the blue line on the graphs, and provide a relative measure of population size on an arithmetic scale relative to an arbitrary value of 100 in one of the years of the sequence. If an index value increases from 100 to 200, the population has doubled; if it declines from 100 to 50, it has halved. The two green lines on the graphs, above and below the index line, are the upper and lower 85% confidence limits. A narrow confidence interval indicates that the index series is estimated precisely, and a wider interval indicates that it is less precise. The use of 85% confidence limits allows relatively straightforward comparison of points along the modelled line: non-overlap of the 85% confidence limits is equivalent to a significant difference at approximately the 5% level ([Anganuzzi 1993](#)).

Caveats are provided to show where the data suffer from a 'Small sample' if the mean number of plots was less than 20. Data are flagged as 'Unrepresentative?' if the average abundance of a species in 10-km squares containing CBC plots was less than that in other 10-km squares of the species' distribution in the UK (as measured from *1988–91 Breeding Atlas* data ([Gibbons \*et al.\* 1993](#))), or, where average abundances could not be calculated, if expert opinion judged that CBC data may not be representative.

In practice most CBC data included in this report have been combined with BBS data to provide joint CBC/BBS trends, using the methods described in the next section. These methods for producing joint trends represent an extension of those described above.

---

## 2.3 Combined Common Birds Census (CBC) and Breeding Bird Survey (BBS) trends

The field protocols for the two surveys are described in sections 2.1 and 2.2. As previously noted, the **CBC** has been an enormously influential project, providing the main source of information on national population levels in the UK since its inception in 1962. Coverage was predominantly in lowland England, where the numbers of potential volunteers are greatest, while coverage was more patchy in more sparsely populated regions and especially the uplands ([Marchant \*et al.\* 1990](#)). CBC plots were situated in a limited number of habitats, predominantly farmland and woodland. Within a large rectangle of southeastern Britain (covering England and Wales south and east from Seascale, Scarborough and Exeter), the plots are nevertheless believed to be broadly representative, at least of lowland land-classes ([Fuller \*et al.\* 1985](#)). For species such as Wood Warbler and Meadow Pipit that have the greater part of their numbers in the far west or north of Britain, however, the CBC may not have accurately reflected UK trends.

The **BBS**, on account of its more rigorous, stratified random sampling design, and its simplicity in the field, produces data that better cover the previously under-represented regions and habitats. In some **early editions** of 'Breeding Birds in the Wider Countryside' (e.g. [Baillie \*et al.\* 2002](#)), separate indices were published from CBC and BBS data, for those species with sufficiently large sample sizes. There being no new CBC data since 2000, however, it is unnecessary to present a CBC-only trend – except for those few species that are now so rare that no joint or BBS index is available.

For most purposes, the presentation and analysis of longer time-series is required, dating back to before the establishment of the BBS but coming right up to the present day. The calculation of 25-year alert designations, as in this report, provides just one example. This need led the BTO to research the compatibility of indices from BBS and CBC data in various years and regions, and the possibility of deriving trustworthy long-term indices from the two data sources in combination ([Freeman \*et al.\* 2003, 2007a](#)). This research suggested that for the vast majority of species considered there was no significant difference between population trends, calculated from the two surveys, based on that part of the country where CBC data are sufficient to support a meaningful comparison. Where a statistically significant difference was found, this was sometimes for very abundant species for which the power to detect even a biologically insubstantial difference was considerable. Within this region, therefore, long-term trends based on CBC and BBS data can be produced for almost all species previously monitored by the CBC alone. For ([Freeman \*et al.\* 2003, 2007a](#)) this was the area covered by [Fuller \*et al.\* \(1985\)](#), because CBC plots in that region were shown to be representative of lowland farmland there. As this region covers the bulk of England, and for consistency with the rest of this report, we have produced joint indices for CBC/BBS for the whole of England (the CBC/BBS England index), rather than just the English part of the 'Fuller rectangle'.

A second question then is whether one can obtain reliable trends over the same period for the entire UK. That is, since prior to 1994 only CBC data are available, are the population trends within the region well covered by the CBC typical of those for the UK as a whole? The shortage of CBC data in the north and west means that the only way of investigating this is via the BBS data. Significant differences in trends between the area well covered by the CBC and the rest of the UK were found for approximately half the species (see [Freeman \*et al.\* 2003, 2007a](#), for full details). For such species, a regional bias in CBC data means that no reliable UK index can be produced prior to 1994. In summary, joint population indices dating back to the start of the CBC can continue to be produced for that part of the country well served by the CBC (essentially England) for almost all common species. However, a similar UK index can be produced for only about 50% of species (CBC/BBS UK index).

This report presents joint CBC/BBS trends for the UK and/or England, as appropriate. Ideally the trends would have been estimated using generalised additive models ([Fewster \*et al.\* 2000](#)) but these were too computationally intensive, given the large number of sites involved. Therefore we fitted a generalised linear model, with counts assumed to follow a Poisson distribution, and a logarithmic link function, to the combined CBC/BBS data. Standard errors were calculated via a bootstrapping procedure and there is therefore no need to model overdispersion, as it does not affect the parameter estimates. BBS squares were weighted by the number of 1-km squares in each sampling region divided by the number of squares counted in that region as in standard BBS trend analyses. CBC plots

were assigned the average weight of all BBS squares as this allows them to be incorporated within the analysis while retaining the convention of not applying weights within the BBS sample. The population trend was smoothed using a thin-plate smoothing spline with degrees of freedom about one third the number of years. Confidence intervals were calculated via a bootstrap procedure. Bootstrap samples were generated by resampling sites from the original data set, with replacement. A generalised linear model was then fitted to each bootstrap replicate and a smoothing spline fitted to the annual population indices as described above. Confidence limits were then calculated as the appropriate percentiles from the sets of smoothed estimates. The overall result is a smoothed trend that is mathematically equivalent to that produced from a generalised additive model. The method of estimation is less statistically efficient because the smoothing is not incorporated within the estimation procedure, and is likely to have resulted in more conservative statistical tests and wider confidence limits. However this compromise was necessary to make it possible to fit the trends within a reasonable amount of computer time (still several weeks).

Indices are plotted as the blue line on the graphs, and provide a relative measure of population size on an arithmetic scale relative to an arbitrary value of 100 in one of the recent years of the sequence. If an index value increases from 100 to 200, the population has doubled; if it declines from 100 to 50, it has halved. Note that positive and negative percentage changes are not directly equivalent: for example, a decrease of 20% would require an increase of 25% to restore the population to its former level. The two green lines on the graphs, above and below the index line, are the upper and lower 85% confidence limits. A narrow confidence interval indicates that the index series is estimated precisely, and a wider interval indicates that it is less precise. The use of 85% confidence limits allows relatively straightforward comparison of points along the modelled line: non-overlap of the 85% confidence limits is equivalent to a significant difference at approximately the 5% level ([Anganuzzi 1993](#)).

**[Next section – 2.4 Waterways Bird Survey and Waterways Breeding Bird Survey](#)**

**[Back to Methodology Index](#)**

---

[BBWC Home](#) > [Contents](#) > [Methodology](#) > [Waterways Bird Survey](#)

## 2.4 Waterways Bird Survey and Waterways Breeding Bird Survey

### Waterways Bird Survey 1974–2007

The Waterways Bird Survey (WBS) monitored the population trends of up to 24 riparian bird species on canals and rivers throughout the UK during the period 1974–2007. WBS used a territory-mapping method like that of its parent scheme, the [Common Birds Census](#), to estimate the breeding population of waterbirds on each of a number of observer-selected survey plots. Detailed territory maps were prepared alongside habitat data that show which features of linear waterways are important to breeding birds. The plots averaged 4.4 km in length; almost half were slow-flowing lowland rivers with the rest either fast-flowing rivers/streams or canals. In the scheme's final years there were around 90 plots distributed throughout the UK. The proportion of plots in the north and west of England was higher than existed in the CBC ([Marchant \*et al.\* 1990](#)). As with CBC, coverage outside England was relatively poor.

All fieldwork was carried out by BTO volunteers. Observers were asked to survey their plots on nine occasions between March and July, mapping all the birds seen or heard onto 1:10,000-scale maps. Registrations were then transferred to species maps, which were analysed to reveal the numbers and positions of territories for each species. For the first 20 years all territory analysis was performed by trained headquarters staff but, during 1994–2007, observers completed their own territory analysis, based on the scheme's written guidelines, with results checked by BTO staff. As WBS employed very similar methods to those of CBC, the validation studies carried out for the latter generally hold true for WBS (see [section 2.2](#)). [Marchant \*et al.\* \(1990\)](#) found that there had been little change by then in the composition of the WBS sample in terms of waterway type or geographical spread.

Population changes along waterways have been reported in *Bird Study* and *BTO News* for up to 24 riparian species. For specialist waterbirds, including [Little Grebe](#), [Mute Swan](#), [Common Sandpiper](#), [Kingfisher](#), [Sand Martin](#), [Grey Wagtail](#), [Dipper](#) and [Reed Warbler](#), targeted surveys along waterways can provide a better precision of monitoring than is possible through the more generalised BBS surveys. [Goosander](#) is not covered at all as yet by BBS monitoring. WBS indices can also add a new perspective on trends in waterbirds that are monitored, largely in different habitats, by CBC/BBS. For [Lapwing](#), populations declined rapidly on arable farmland during the late 1980s while numbers on WBS plots, typically representing populations along river floodplains, were more stable. [Yellow Wagtails](#) have declined much more steeply in WBS habitats than elsewhere.

### Waterways Breeding Bird Survey and joint indices

WBS had similar limitations as a monitoring scheme that led to the CBC's replacement by BBS. In particular, plot distribution was biased geographically and possibly also towards sites that were good for birds, and an intensive survey method was used that severely limited the sample size ([Marchant \*et al.\* 1990](#)). A drawback specific to WBS was that it covered only waterbirds.

BTO addressed these issues by setting up the [Waterways Breeding Bird Survey \(WBBS\)](#), which ran in parallel with WBS from 1998 to 2007. WBBS uses BBS-style transect methods along random waterways, and includes all species of birds (and mammals, too). WBBS is currently funded by the Environment Agency. Following the closure of WBS after the 2007 season, it is now expected that WBBS will become an ongoing part of the BTO's core monitoring, providing useful monitoring data to supplement BBS.

In a similar development to joint CBC/BBS indices, it has proved possible to link the two waterways schemes to provide joint WBS/WBBS indices, some dating back to 1974, for the species previously covered by WBS (see below).

### Data analysis

Population trends are generated from the combined WBS and WBBS data using a Generalised Linear Model with counts assumed to follow a Poisson distribution and a logarithmic link function. Standard errors were calculated via a bootstrapping procedure involving 199 bootstraps. For presentation in the figures, both the population trend and its confidence limits were also subsequently smoothed using a thin-plate smoothing spline. The overall result is a smoothed trend that is mathematically equivalent to

that produced from a generalised additive model, as previously used in earlier reports for the WBS data alone.

[Next section – 2.5 Heronries Census](#)

[Back to Methodology Index](#)

[WBS](#) and [WBBS](#) sections of the main BTO web site

---

[BBWC Home](#) > [Contents](#) > [Methodology](#) > [Heronries](#)

## 2.5 Heronries Census

The BTO Heronries Census began in 1928 and is the longest-running breeding-season bird monitoring scheme in the world. As predators at the top of the freshwater food chain, Grey Herons are excellent indicators of environmental health in the countryside. They build large stick nests, mostly in colonies at traditional sites. The aim of this census is to collect annual nest counts of Grey Herons from as many sites as possible in the United Kingdom. Volunteer observers make counts of 'apparently occupied nests' at heron colonies each year. Changes in the numbers of nests, especially over periods of several years, provide a clear measure of the population trend.

In recent seasons, observers have also counted the nests of **Little Egrets** *Egretta garzetta*, which have been appearing in an increasing number of southern heronries since the first breeding records in 1996, and even of Cattle Egrets *Bubulcus ibis*. Since egrets are fully included in the Heronries Census, data are required from all breeding sites, whether or not Grey Herons are also present. Counts of **Cormorant** colonies, which often occur alongside heronries, are also welcome ([Newson et al. 2007](#)).

Coverage is coordinated through a network of regional organisers. A core of birdwatchers and ringers monitor their local colonies annually, providing a backbone of regular counts. Around two-thirds of the heronries in England and Wales are currently counted each year, with more-complete censuses carried out in 1929, 1954, 1964, 1985 and 2003. Historically rather few counts have been made of heronries in Scotland and Northern Ireland, except during the special surveys, but support for the Heronries Census has been growing fast in recent years. Counts are submitted mostly on cards and the data are entered onto computer at BTO headquarters. The number of heronries counted each year has grown in recent years to more than 500.

### Data analysis

Population changes are estimated using a ratio-estimators approach derived from that of [Thomas \(1993\)](#). Essentially, the ratios of the populations in any two (not necessarily consecutive) years of the survey are estimated from counts at sites visited in each of those years. These ratios can be used to estimate the counts at sites that were not visited, and hence build an estimate of the total population. Further modifications have been made to allow for the extinction of colonies and the establishment of new ones ([Marchant et al. 2004](#)).

On the [Grey Heron](#) page of this report, the UK trend is presented graphically with annual estimates in blue and their 85% confidence limits in green. A smooth trend line in red is based on a non-parametric regression model, using thin-plate smoothing splines with 24 degrees of freedom. Trends are also shown for England and Wales together, and for England, Wales and Scotland alone.

[Next section – 2.6 Constant Effort Sites Scheme](#)

[Back to Methodology Index](#)

[CLICK HERE](#) to visit the Little Egret page of the main BTO website (WeBS)

---

[BBWC Home](#) > [Contents](#) > [Methodology](#) > [Constant Effort Sites](#)

## 2.6 Constant Effort Sites Scheme

The Constant Effort Sites (CES) Scheme uses changes in catch sizes across a network of standardised mist-netting sites to monitor changes in the abundance and breeding success of common passerines in scrub and wetland habitats. At each constant effort site, licensed ringers erect a series of mist nets in the same positions, for the same amount of time, during 12 visits evenly spaced between May and August. Year-to-year changes in the number of adults caught provide a measure of changing population size, while the ratio of young birds to adults in the total catch is used to monitor annual productivity (breeding success). By monitoring the abundance of young birds between May and August, the CES method should integrate contributions to annual productivity from the entire nesting season, including second and third broods for multi-brooded species, but will also include a small component of mortality during the immediate post-fledging period. Between-year recaptures of ringed birds can also be used to calculate annual survival rates of adult birds, although this requires specialised analytical techniques (e.g. [Peach 1993](#)) and is not considered further here. Further details of the CES Scheme are presented by [Peach \*et al.\* \(1996\)](#) and methods of analysis are detailed in [Peach \*et al.\* \(1998\)](#) for abundance measures and [Robinson \*et al.\* \(2007\)](#) for productivity measures.

The CES Scheme began in 1983 with 46 sites and now has around 120. The distribution of CES sites tends to reflect the distribution of ringers within Britain and Ireland. The majority are operated in England, and there are small numbers in Scotland, Wales, Northern Ireland and the Republic of Ireland. The CES routinely monitors the populations of 25 species of passerines in scrub and wetland habitats.

### Data analysis

Smoothed trends in the abundance of adults and young are separately assessed using a generalised additive model (GAM), with 85% confidence intervals calculated by bootstrapping ( [Fewster \*et al.\* 2000](#)). At sites where catching effort in a year falls below the required 12 visits, but eight or more visits have been completed, annual catch sizes are corrected according to experience during years with complete coverage, by incorporating an offset into the GAM (see [Peach \*et al.\* \(1998\)](#) for full details). Sites with fewer than eight visits in a given year are omitted for the year in question. Annual indices of productivity (young per adult) are estimated from logistic regression models applied to the proportions of juvenile birds in the catch, the year-effects then being transformed to measures of productivity relative to an arbitrary value of 100 in the most recent year. As above, catch sizes are corrected where small numbers of visits have been missed. It should be noted that these indices are relative, and are not estimates of the actual numbers of young produced per adult ([Robinson \*et al.\* 2007](#)).

Data are presented graphically with the smoothed trend in blue and their 85% confidence limits in green. A caveat is provided for 'Small samples' when the average number of plots per year is between 10 and 20.

Annual estimates of adult survival are derived from a form of the standard CJS capture–mark–recapture model ([Lebreton \*et al.\* 1992](#)) modified to account for the presence of transient birds. Transients are birds passing through the site, or perhaps living on its periphery, and which therefore have a much lower probability of capture than resident birds living in the vicinity of the nets. The presence of transients thus tends to decrease the estimated survival rates. We allow for this by introducing an additional 'survival period' in the year of first capture: birds recaptured subsequently survive this period and birds which are not recaptured do not. Thus we assume that birds recaptured more than once (in the same or subsequent years) are resident; those that are not may be resident, or transient, with a probability equal to the survival during the additional initial period. The annual estimates of survival presented are in fact the probability that adult birds return to the same CE site the following year; this will be lower (to a small but unknown extent) than the true survival rate. We do not estimate survival rates for juvenile birds, because of their much greater dispersal distances.

[Next section – 2.7 Nest Record Scheme](#)

[Back to Methodology Index](#)

## 2.7 Nest Record Scheme

The BTO's Nest Record Scheme is the largest, longest-running and most highly computerised of such schemes in the world and possesses the most advanced and efficient techniques of data gathering, data capture and analysis ([Crick \*et al.\* 2003](#)). There are now more than a million nest records held by the Trust, of which 35% are computerised.

The primary aim of the Nest Record Scheme is to monitor the breeding performance of a wide range of UK birds annually as a key part of the BTO's data collection. Annual reports are published in *BTO News* (e.g. [Leech & Barimore 2008](#)) and the significant results communicated immediately to JNCC. Another primary aim is to undertake detailed analyses of breeding performance of species of conservation interest (e.g. [Crick \*et al.\* 1994](#), [Brown \*et al.\* 1995](#), [Peach \*et al.\* 1995a](#), [Crick 1997](#), [Chamberlain & Crick 1999](#), [Siriwardena \*et al.\* 2001](#), [Crick \*et al.\* 2002](#), [Chamberlain & Crick 2003](#), [Freeman & Crick 2003](#), [Browne \*et al.\* 2005](#), [Tryjanowski \*et al.\* 2006](#)).

The Nest Record Scheme gathers data on the breeding performance of birds in the UK through a network of volunteer ornithologists. Each observer is given a code of conduct that emphasises the responsibility of recorders towards the safety of the birds they record and explains their legal responsibilities. These observers complete standard nest record cards for each nest they find, giving details of nest site, habitat, contents of the nest at each visit and evidence for success or failure. When received by the BTO staff, the cards are checked, sorted and filed away ready for input and analysis. Those for Schedule 1 species are kept confidential. (These are species protected from disturbance at the nest by Schedule 1 of the [Wildlife & Countryside Act 1981](#): they are generally rare species and the location of their nests may need to be protected from egg collecting (an illegal activity) or other potential disturbance. To visit the nests of these species a special licence is required.) Computer programs developed by BTO check the data for errors and calculate first-egg date, clutch size, nest loss rates at egg and chick stages. Data are computerised according to priorities for population monitoring and for specific research projects.

Currently the BTO collects a total of more than 30,000 records each year for around 180 species. Typically, there are more than 150 records for 55 species and more than 100 for a further 10–15 species. The quality of records improved substantially in 1990 with the introduction of a new recording card, which promotes greater standardisation and clarity in the information recorded by observers. The general distribution of Nest Record Cards is patchy at the county scale but is more even over larger regions of the UK. Overall, Northern Ireland and parts of Scotland (southeast, Western Isles) and parts of England (West Midlands, southwest) have relatively low coverage, often reflecting observer density. A major analysis of trends over time in various aspects of breeding performance found relatively few differences between major regions in the UK, when analysed using analysis of covariance ([Crick \*et al.\* 1993](#)). Habitat coverage is broad, as the scheme receives records from all the UK's major habitats. Most records come from woodland, farmland and freshwater sites, but the scheme also receives data from scrub, grassland, heathland and coastal areas.

### Data analysis

Five different variables were analysed for this report: laying date (where day 1 = January 1); clutch size; brood size; and daily nest failure rates during egg and nestling stages, calculated using the methods of [Mayfield \(1961, 1975\)](#) and [Johnson \(1979\)](#) (see [Crick \*et al.\* 2003](#) for a review).

To minimise the incidence of errors and inaccurately recorded nests, a set of rejection criteria was applied to the data: laying date included only cases where precision was within  $\pm 5$  days; clutch size was not estimated for nests which had been visited only once, for nests which were visited when laying could still have been in progress, or for nests which were visited only after hatching; and maximum brood size was calculated only for nests which were observed after hatching. The last variable is an underestimate of brood size at hatching, because observers may miss early losses of individual chicks; it differs from clutch size because eggs may be lost during incubation and hatching success may be incomplete.

Daily failure rates of whole nests were calculated using a formulation of [Mayfield's \(1961, 1975\)](#) method as a logit-linear model with a binomial error term, in which success or failure over a given number of days (as a binary variable) was modelled, with the number of days over which the nest was

exposed during the egg and nestling periods as the binomial denominator ([Crawley 1993](#), [Etheridge \*et al.\* 1997](#), [Aebischer 1999](#)). Number of exposure days during the egg and nestling periods was calculated as the midpoint between the maximum and minimum possible, given the timing of nest visits recorded on each Nest Record Card (note that exposure days refer only to the time span for which data were recorded for each nest and do not represent the full length of the egg or nestling periods). Each calculation assumes that failure rates were constant during the period considered. Violations of this assumption of the Mayfield method can lead to biased estimates if sampling of nests is uneven over the course of each period. It is unlikely that any such bias would vary from year to year, so although absolute failure rates may be biased, annual comparisons should be unaffected ([Crick \*et al.\* 2003](#)). In this report, therefore, we present only temporal trends in daily nest failure rates.

As the combined influence of concurrent trends in these individual breeding parameters on overall productivity is difficult to assess, the estimates produced are used to derive an annual mean estimate of the number of 'fledglings produced per breeding attempt' (FPBA) according to the equation below ([Crick \*et al.\* 2003](#)):

$$FPBA = CS \times HS \times (1 - EF)^{EP} \times (1 - YF)^{YP}$$

where CS represents clutch size, HS represents hatching success, EF and YF represent egg- and chick-stage daily failure rates and EP and YP represent the length of the egg and nestling periods. Standard errors were derived using the formula given by [Siriwardena \*et al.\* \(2000b\)](#).

Statistical analyses of nest record data were undertaken using SAS programs ([SAS 1990](#)). Regressions through annual mean laying dates, clutch sizes and brood sizes were weighted by sample size. Nest survival was analysed by logistic regression. Quadratic regressions were used when the inclusion of a quadratic term provided a significant improvement over linear regression. These are described as 'curvilinear' in the tables on species pages. Significant linear trends are described as 'linear'. The best-fitting regressions (i.e. quadratic or linear) are presented on the figures in this report. Where neither regression is significant the linear regression line is shown for illustrative purposes.

Results are presented only if the mean sample size of records for a particular variable and species exceeds ten per year, and are presented with a caveat for small sample sizes if the mean number of records contributing data was between ten and 30 per year.

## 2.8 The alert system

### 2.8.1 General approach

### 2.8.2 Smoothing population trends

### 2.8.3 Years used for analysis

### 2.8.4 Confidence limits and statistical testing

### 2.8.5 Data-deficient species

#### 2.8.1 General approach

The alert system used within this report is designed to draw attention to developing population declines that may be of conservation concern, and is described in detail by [Baillie & Rehfisch \(2006\)](#). It also identifies situations where long-term declines have reversed, leading to an improvement in conservation status. It must be stressed that the changes reported here are advisory and do not supersede the agreed UK conservation listings ([Eaton et al. 2009](#); see [PSoB](#) pages). They are based on similar criteria to *Birds of Conservation Concern*, however, and so provide an indication of likely changes at future revisions.

The system is based on statistical analyses of the population trend data for individual species. Alerts seek to identify rapid declines (>50%) and moderate declines (>25% but <50%). These declines are measured over a number of time-scales, depending on the availability of data – the full length of the available time series, and the most recent 25 years, 10 years and 5 years for which change can be estimated. The conservation emphasis is particularly on the longer periods, but short-term changes help to separate declines that are continuing – or accelerating – from those that have ceased or reversed.

The alerts are calculated annually using standard automated procedures. Where species are at the margin of two categories (e.g. a decline of about 25%) they may fire alerts in some years but not others, or different levels of alert in different years.

Data on some species might be biased, owing to possibly unrepresentative monitoring, or imprecise, owing to small sample sizes. Because these data often provide the only information that is available, our general approach is to report all the alerts raised but to flag up clearly any deficiencies in the data.

#### 2.8.2 Smoothing population trends

Bird populations show long-term changes that do not follow simple mathematical trajectories. In addition to the long-term trends, unsmoothed population indices also show short-term fluctuations resulting from a combination of natural population variability and statistical error. We use smoothing techniques that aim to extract the long-term pattern of population change, without forcing it to follow any particular shape (such as a straight line or a polynomial curve). These methods remove most of the effects of short-term fluctuations (including any natural year-to-year variability) so that the long-term trend is revealed more clearly.

#### [Technical details available here](#)

#### 2.8.3 Years used for analysis

Once a smoothed population trend has been calculated, change measures are calculated from the ratio of the smoothed population indices for the two years of interest. Population indices for the first and last years of a smoothed time series are less reliable than the others, and so we always drop them before calculating alerts. Because the latest year is not included, the alerts are therefore less up-to-date than they could be, but fewer false alarms are generated. The latest year's data points do contribute to the smoothed curve and are dropped only after the smoothing has taken place.

The time it takes BTO to collate and analyse bird monitoring data is another factor affecting the years that can be included in these analyses. Full analyses of data sets are not usually all available until 12–15 months after the end of a particular breeding season. Thus for a report prepared in year  $x$  (e.g. 2009) we have analyses of monitoring data up to year  $(x-1)$  (e.g. 2008). As we drop the final year of the

smoothed time series, we report here on change measures up to year (x-2) (e.g. 2007).

Long-term changes for most of the species included in this report are calculated from joint Common Birds Census and Breeding Bird Survey data (CBC/BBS indices). The CBC started on farmland in 1962 and on woodland in 1964. However, the early years of the CBC population indices are strongly influenced by the effects of the unusually severe winters of 1961/62 and 1962/63, as well as by developments in methodology ([Marchant \*et al.\* 1990](#)). Joint CBC/BBS indices have been calculated using only the data from 1966 onwards, therefore, and population changes are calculated back to 1967.

#### 2.8.4 Confidence limits and statistical testing

We show 90% confidence limits for population change measures wherever possible. Any decline where the confidence limits do not overlap zero (no change) is regarded as statistically significant and will trigger an alert if it is of sufficient magnitude. Note that, because we are seeking to detect only declines, we are using a one-tailed test – with a *P* value of 0.05. These confidence limits therefore do not indicate whether increases are statistically significant.

The graphs of population trends show 85% confidence limits because these allow an approximate visual test of whether the difference between the index values for any two given years is statistically significant: if the index values for two given years are assumed to be independent, and normally distributed with standard errors of comparable size (standard errors differing by a factor of up to about 2 are quite acceptable), then to a good approximation the difference between them is significant at the 5% level if there is no overlap in their 85% confidence intervals ([Buckland \*et al.\* 1992](#), [Anganuzzi 1993](#)). This test is fairly robust, and the independence assumption is reasonable if the years are well separated.

[Technical details available here](#)

#### 2.8.5 Data-deficient species

There is uncertainty about the reliability of the results for some species, either because data may be unrepresentative or because they are based on a very small sample of plots. In these cases the cause of the uncertainty is recorded in the comment column of the population change table.

##### ***Unrepresentative data***

In this report we present joint UK or England CBC/BBS trends only if there was no substantial or statistical difference between the trends from the two schemes over the period when they ran in parallel. Thus, since BBS results are drawn from a random sample, the trends are always considered to be representative of the region concerned.

In previous reports representativeness was assessed using the criteria developed by [Gibbons \*et al.\* \(1993\)](#). Data from the 1988–91 Breeding Atlas were used to compare the average abundance of a given species in 10-km squares with and without CBC plots. If average abundance is higher in squares without CBC plots, it is likely that much of the population is not well sampled by the CBC. In past reports, CBC data for such species were labelled as "unrepresentative". Where there are insufficient data to undertake such calculations, expert opinion was used instead.

##### ***Sample size***

Sample size is assessed from the average number of plots contributing to the population indices for a given species in each year. A plot with a zero count would be included provided that the species had been recorded there in at least one year and that records for that plot were available for at least two years. Plots where a species has never been recorded do not enter the index calculations. These average sample sizes are shown in column four (plots) of the population change tables. For CBC, WBS and CES, a mean of between 10 and 19 plots is flagged as a small sample. For BBS indices for individual countries a mean in the range 30–39 plots is flagged as a small sample. UK BBS indices are presented only where samples reach at least 40 plots.

## 2.9 Statistical methods used for alerts

The [Alert System](#) page contains a general overview of how the alert system works. More detailed information is given below about the statistical methods used to estimate population indices, population changes and their confidence intervals.

### 2.9.1 General structure of data and models

#### 2.9.2 Fitting smoothed models

#### 2.9.3 CBC/BBS trends

#### 2.9.4 WBS/WBBS trends

#### 2.9.5 Constant Effort Sites Scheme

#### 2.9.6 Heronries Census

### 2.9.1 General structure of data

The data for all of the schemes reported here consist of annual counts made over a period of years at a series of sites. They can thus be summarised as a data matrix of sites x years, within which a proportion of the cells contain missing values because not all of the sites are covered every year. Such data can be represented as a simple model:

$$\log(\text{count}) = \text{site effect} + \text{year effect}$$

Each site has a single site-effect parameter. These site parameters are not usually of biological interest but they are important because abundance is likely to differ between sites. The main parameters of interest are the year effects. These can be modelled either with as many parameters as years (an annual model), or with a smaller number of parameters, representing a smoothed curve.

A simple annual model would be fitted as a generalised linear model with Poisson errors and a log link function. This is the main model provided by the program TRIM ([Pannekoek & van Strien 1996](#)), which is widely used for population monitoring.

### 2.9.2 Fitting smoothed models

Our preferred method for generating a smoothed population trend is to fit a smoothed curve to the data directly using a generalised additive model (GAM) ([Hastie & Tibshirani 1990](#), [Fewster \*et al.\* 2000](#)). Thus the model from the previous section becomes:

$$\log(\text{count}) = \text{site effect} + \text{smooth}(\text{year})$$

where  $\text{smooth}(\text{year})$  represents some smoothing function of year. It was not straightforward to fit GAMs to the CBC/BBS or Heronries Census data and we have therefore fitted smooth curves with a similar degree of smoothing to the annual indices (details below).

The non-parametric smooth curve fitted in our models is based on a smoothing spline. The degree of smoothing is specified by the number of degrees of freedom (df). A simple linear trend has  $df = 1$ , whereas the full annual model has  $df = t - 1$ , where  $t$  is the number of years in the time series. Here we set  $df$  to be approximately 0.3 times the number of years in the time series ([Fewster \*et al.\* 2000](#)). The degrees of freedom used for the main data sets presented in this report are summarised below.

	Years	Length of time series	df for smoothed index
<a href="#">CBC/BBS</a>	1966–2008	44	13
<a href="#">Waterways Bird Survey</a>	1974–2008	36	11
<a href="#">Constant Effort Sites</a>	1983–2008	27	8
<a href="#">Heronries Census</a>	1928–2008	82	25

Note that the numbers of years shown here are different from those available for calculating change measures, because we use the whole time series available for analysis (i.e. prior to the truncation of end points), and because we count the number of years in the time series rather than the number of

annual change measures.

### 2.9.3 CBC/BBS trends

The model fitted to the combined CBC and BBS data is that historically employed for the BBS, a Generalised Linear Model with counts assumed to follow a Poisson distribution and a logarithmic link function. Standard errors were calculated via a bootstrapping procedure. For presentation in the figures, both the population trend and its confidence limits were also subsequently smoothed using a thin-plate smoothing spline. The overall result is a smoothed trend that is mathematically equivalent to that produced from a generalised additive model.

A similar method as employed for the joint CBC/BBS trend has been used for the BBS alone. This adopted a Generalised Linear Model with counts assumed to follow a Poisson distribution and a logarithmic link function. Standard errors were calculated via a bootstrapping procedure involving 199 bootstraps. For presentation in the figures, both the population trend and its confidence limits were also subsequently smoothed using a thin-plate smoothing spline.

### 2.9.4 WBS/WBBS trends

The model fitted to the combined WBS and WBBS data is identical to that employed for the joint CBC/BBS trend, a Generalised Linear Model with counts assumed to follow a Poisson distribution and a logarithmic link function. Standard errors were calculated via a bootstrapping procedure involving 199 bootstraps. For presentation in the figures, both the population trend and its confidence limits were also subsequently smoothed using a thin-plate smoothing spline. The overall result is a smoothed trend that is mathematically equivalent to that produced from a generalised additive model, as previously used in earlier reports for the WBS data alone.

### 2.9.5 Constant Effort Sites

GAMs were fitted to the CES data for catches of adults and juveniles separately with the addition of an offset to correct for missing visits. Confidence limits were fitted using a bootstrap technique to avoid restrictive assumptions about the distribution of the data. Bootstrap samples were drawn from the data by sampling plots with replacement. We generated 199 bootstrap samples from each data set and fitted a GAM to each of them. Confidence limits for the smoothed population indices (85% ci) and change measures (90% ci) were determined by taking the appropriate percentiles from the distributions of the bootstrap estimates, in a similar manner to that employed for the WBS/WBBS trends.

### 2.9.6 Heronries Census

The Heronries Census data were analysed using a modified sites x years model based on ratio estimation which incorporates information about new colonies (sites) that have been established and other colonies from the sample that are known to have gone extinct. The method was developed by [Thomas \(1993\)](#) specifically in relation to the heronries data set. Since then the heronries database has been substantially upgraded and the method has been applied to the full data set ([Marchant \*et al.\* 2004](#)).

The above method of analysis cannot be easily applied within a GAM framework. Therefore we fitted a smooth curve to the annual indices. This was done using PROC TSPLINE of SAS. This procedure should give very similar estimates to a GAM analysis but it does not provide confidence intervals for the smoothed population trend or the change measures derived from it. This is not a serious limitation as there are no potential alerts for [Grey Heron](#), whose populations have generally been increasing.

## MUTE SWAN

*Cygnus olor*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (concentrated in Europe, conservation status favourable)

UK: green

### Long-term trend

UK, England: rapid increase

### UK population size

28,000–30,000 adults in 1990 ([Delany et al. 1992: APEP06](#)); 23,900–25,600 pairs in 2000 (updated using CBC/BBS trend: [BiE04](#)); 28,600–35,200 birds in Britain in 2002 ([Rowell & Spray 2004](#))

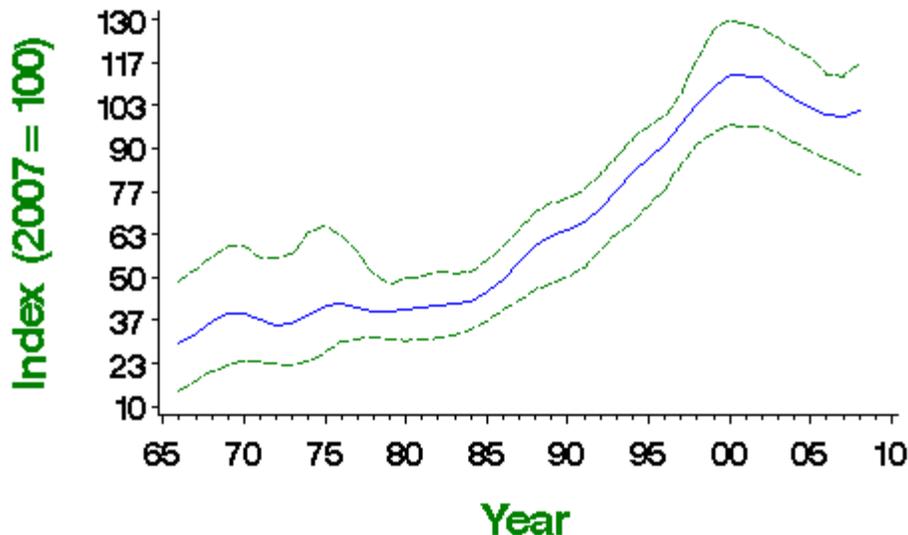

### Status summary

Mute Swan populations, which had been fairly stable since the 1960s, have increased progressively since the mid 1980s, perhaps reflecting warmer winter weather and the replacement of anglers' lead weights, which had earlier caused many cases of lethal and sublethal poisoning, with non-toxic alternatives ([Rowell & Spray 2004](#), [Ward et al. 2007](#)). Waterways, likely to be a preferred habitat for breeding swans, show a more moderate rate of increase than CBC/BBS. Winter trends as measured by WeBS have shown a parallel upturn ([Holt et al. 2009](#)). The increase in egg-stage nest failure rates, although statistically significant, may be to some extent an artefact of the relatively small and perhaps unrepresentative annual samples in the 1990s. After a spell on the amber list from 2002, for reasons unconnected with its UK trend, the species is now green listed once more.

## GREYLAG GOOSE

*Anser anser*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)  
 UK: not listed (introduced population);  
 amber (localised NW Scottish population);  
 amber (in winter, localised and >20% of NW European Flyway population)

### Long-term trend

UK waterways: rapid increase

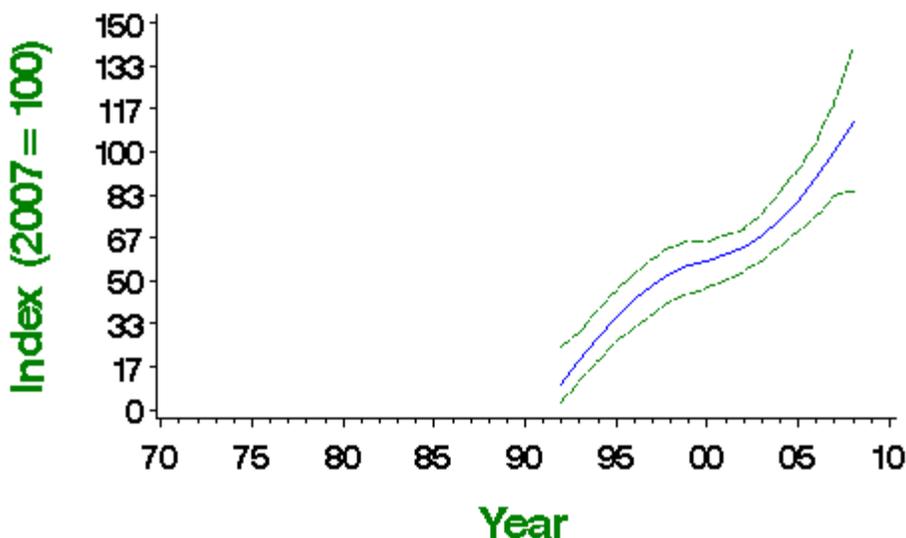

### UK population size

3,200 indigenous pairs in 1997, and 30,900 introduced adults in 1999 (Mitchell *et al.* 2000, Rehfishch *et al.* 2002, APEP06); 15,600–15,800 pairs in 2000 (BiE04)

### Status summary

Apart from a small indigenous population in northwest Scotland and the Western Isles, and winter visitors mainly from Iceland, the Greylag Goose is an introduced species throughout the UK. Introduced Greylags increased very rapidly, at a rate estimated at 12% per annum in southern Britain between the 1988–91 Atlas period and 1999 (Rehfishch *et al.* 2002). This equates across Britain to 170%, or 9.4% per annum, in the period to 2000 (Austin *et al.* 2007). The WBS sample became large enough for annual monitoring in 1992, since when further steep increase has been recorded along linear waterways with no sign yet of levelling off. Annual breeding-season monitoring in a wider range of habitats through BBS has shown similar strong increases. Winter counts confirm that the introduced population is likely to be already much larger than the latest agreed population estimates, based on surveys in 1999 and 2000 (Holt *et al.* 2009).

### WBS/WBBS 1992–2008 Greylag Goose

## CANADA GOOSE

*Branta canadensis*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: not listed (introduced)

### Long-term trend

UK waterways: rapid increase

### UK population size

82,550 adults in 1999 ([Rehfishch et al. 2002: APEP06](#));

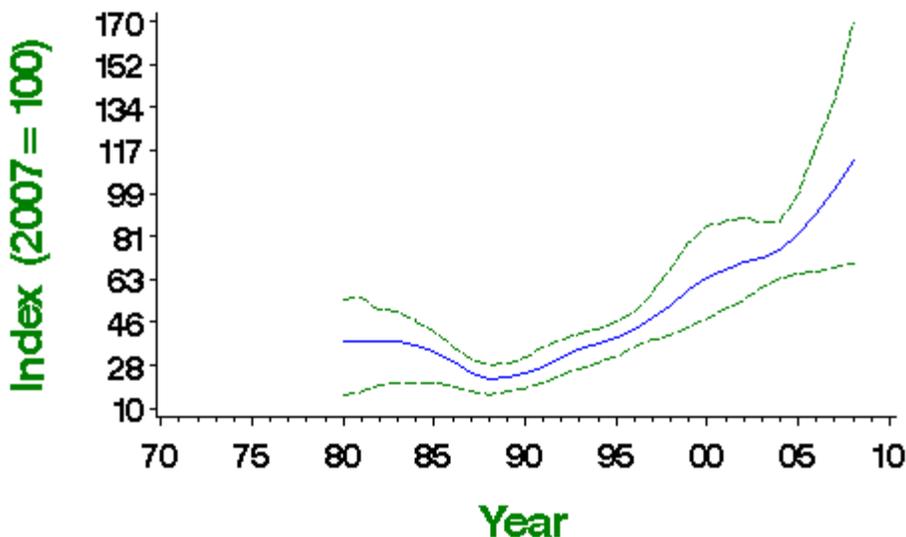

88,866 adults in Britain in 2000 ([Austin et al. 2007](#))

### Status summary

Canada Geese were first introduced to English parkland around 1665 but have expanded hugely in range and numbers following translocations in the 1950s and 1960s. They increased rapidly, at a rate estimated at 9.3% per annum in Britain between the 1988–91 Atlas period and 2000, with no sign of any slowing in the rate of increase ([Austin et al. 2007](#)). Most of this increase, amounting to 166% during that decade alone, has been in areas previously with low goose densities. The WBS sample became large enough for annual monitoring in 1980, since when further, apparently accelerating, increase has occurred on linear waterways. Annual breeding-season monitoring in a wider range of habitats through BBS has shown similar strong increases in England and in the UK as a whole. Winter monitoring by WeBS shows a continuing long-term increase ([Holt et al. 2009](#)). The economic, social and environmental impacts of rapidly expanding, non-native Canada Goose populations are of growing conservation concern across Europe.

### WBS/WBBS 1980–2008 Canada Goose

## MALLARD

### *Anas platyrhynchos*

• Population changes

• Productivity trends

• Additional information

#### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: amber (winter decline)

#### Long-term trend

UK, England: rapid increase

#### UK population size

50,400–127,100 pairs in 1990 (1988–91 Atlas: [APEP06](#)); 63,000–158,900 pairs in 2000 (updated using CBC/BBS trend: [BiE04](#))

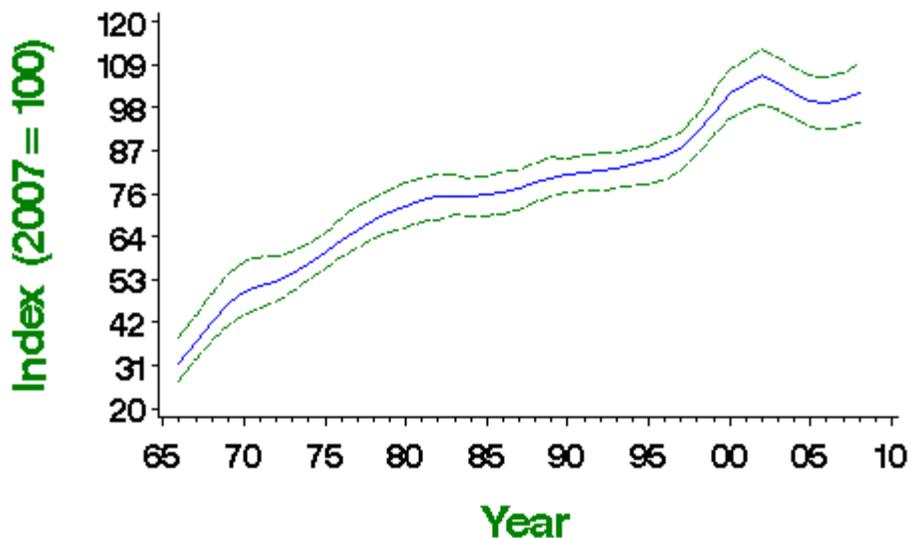

#### Status summary

The Mallard has increased steadily as a breeding bird in the UK since the 1960s, and especially in England, a trend to which ongoing large-scale releases for shooting may have contributed ([Marchant et al. 1990](#)). Mallards originating from domesticated birds and not resembling wild-type birds in either plumage or behaviour are very abundant but perhaps under-represented in survey data, especially since many individuals appear to be semi-captive. A large part of the increase in breeding numbers may be attributable to such birds, rather than to true-bred stock. Winter populations have declined since at least the late 1980s ([Holt et al. 2009](#)), linked apparently to a decrease in continental immigration ([Mitchell et al. 2002](#)). The species has recently been moved from the green to the amber list on the strength of this decline in the UK wintering population.

## TUFTED DUCK

*Aythya fuligula*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: SPEC category 3 (declining)

UK: amber (European decline)

### Long-term trend

UK waterways: rapid increase

### UK population size

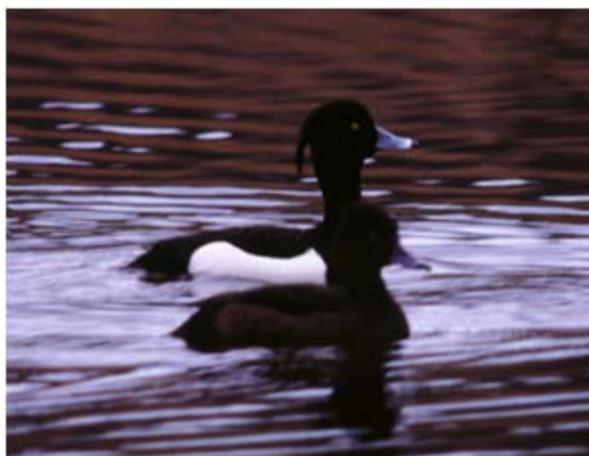

7,000–8,000 pairs in GB in 1979–83 ([Owen et al. 1986](#);

[APEP06](#)); 10,200–11,500 pairs in UK in 2000 (1988–91

Atlas estimate updated using WBS trend: [BiE04](#))

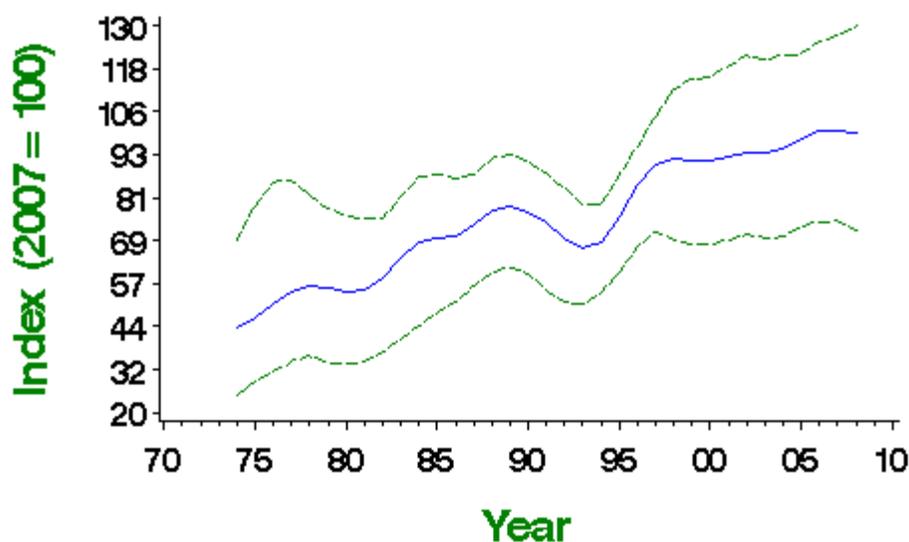

### Status summary

The colonisation of the UK by Tufted Ducks, which began in 1849, was aided by the spread of the zebra mussel *Dreissena polymorpha*, a non-native invasive species that had been introduced accidentally to Britain a few decades earlier. The long-term increase shown by WBS/WBBS, and the 15% increase in range in Britain between the two atlas periods ([Gibbons et al. 1993](#)) indicate that population expansion and in-filling of range are still occurring. BBS data also show significant increase since 1994 in the UK as a whole. The species' winter trend in the UK since the 1960s, which includes many continental visitors, is also shallowly upward overall ([Holt et al. 2009](#)). In contrast, moderate recent declines elsewhere in northern Europe have resulted in its reclassification as a species of conservation concern ([BirdLife International 2004](#)) and have moved the species from the green to the amber list in the UK ([Eaton et al. 2009](#)).

## GOOSANDER

### *Mergus merganser*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: green

### Long-term trend

UK waterways: moderate increase

### UK population size

2,600 (2,300–2,900) pairs in 1987 (Gregory *et al.* 1997: APEP06); 2,900–3,600 pairs in 2000 (updated using WBS trend: BiE04)

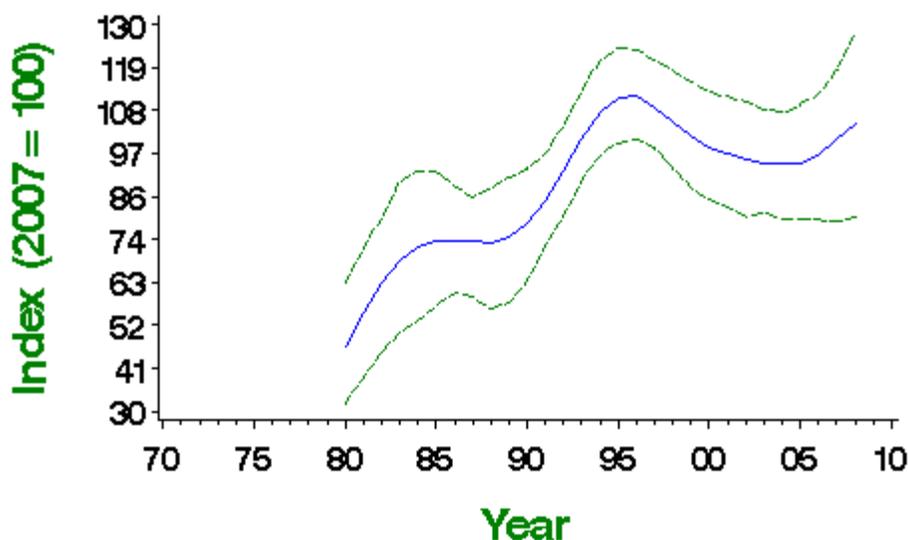

### Status summary

Goosanders were first discovered to have colonised the UK in Perthshire in 1871, and spread from Scotland into northern England in the 1940s (Holloway 1996). Between the two breeding atlases, the species expanded its range in northern England, and colonised Wales and southwest England. WBS samples became large enough for annual monitoring in 1980, and showed sustained population increase, although this may now have levelled off. The BTO's two national surveys of sawbills demonstrated an average increase in population size of 3% per annum between 1987 and 1997 (Rehfishch *et al.* 1999). Reasons for the colonisation of the UK, and the subsequent range expansion and population increase, are unknown. The species' winter trend in Britain, comprising British breeders and continental visitors, rose at an accelerating rate from the late 1960s to the mid 1990s, but subsequently began to decline (Holt *et al.* 2009).

## RED GROUSE

*Lagopus lagopus*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: amber (25–50% population decline)

UK Biodiversity Action Plan: priority species

### Long-term trend

UK: decline

### UK population size

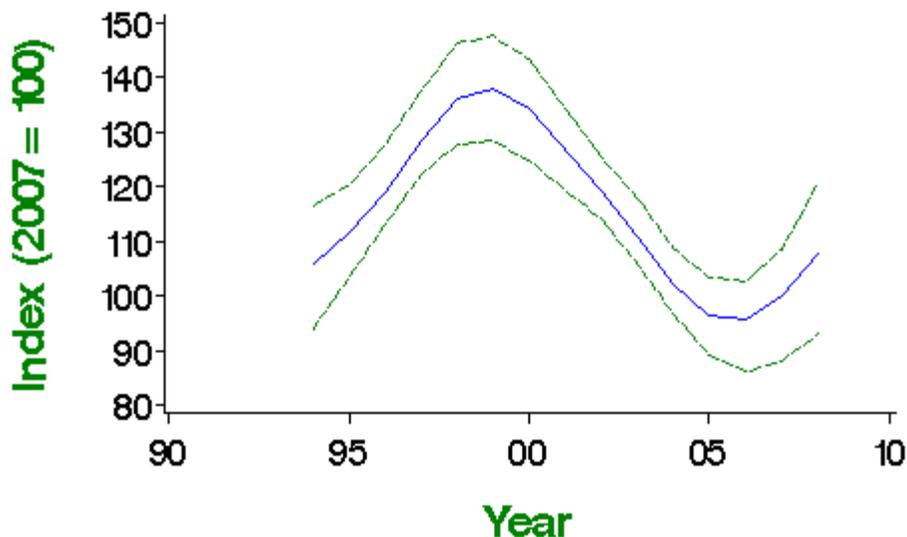

155,000 pairs in 2000 (1988–91 Atlas estimate updated using GCT gamebag data: [BiE04](#), [APEP06](#))

### Status summary

The distinctive dark-winged race *scotica* is endemic to Britain and Ireland and has the vast bulk of its population within the UK, thus conferring global significance to the UK trend. It is economically very important to some rural communities as a game bird and has benefited from intensive management of many moorlands that was designed specifically to increase the numbers of grouse available to be shot. BBS shows fluctuations but no overall trend since 1994. **Shooting bags** have revealed long-term declines, apparently driven by loss of heather moorland, increased predation from corvids and foxes, and an increasing incidence of viral disease ([Hudson 1992](#), [Newton 2004](#)), which prompted the move of the species from the green to the amber list in 2002. Longer-term trends in Red Grouse abundance are overlain by cycles, with periods that vary regionally, linked to the dynamics of infection by a nematode parasite ([Dobson & Hudson 1992](#), [Gibbons \*et al.\* 1993](#)). Raptor predation is believed not to affect breeding populations significantly, although it can reduce numbers in the post-breeding period ([Redpath & Thirgood 1997](#)). **Hen Harriers** in particular can reduce grouse shooting bags, limit grouse populations and cause economic losses to moor owners, and have been subject to much illegal persecution ([Thompson \*et al.\* 2009](#)). Finding a solution to the harrier–grouse conflict would bring considerable benefits to the management of the UK's heather moorlands and have broad implications for the conservation of predators ([Redpath & Thirgood 2009](#)).

## RED-LEGGED PARTRIDGE

*Alectoris rufa*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: SPEC category 2 (declining)

UK: not listed (introduced)

### Long-term trend

UK, England: possible shallow decline

### UK population size

72,000–200,000 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

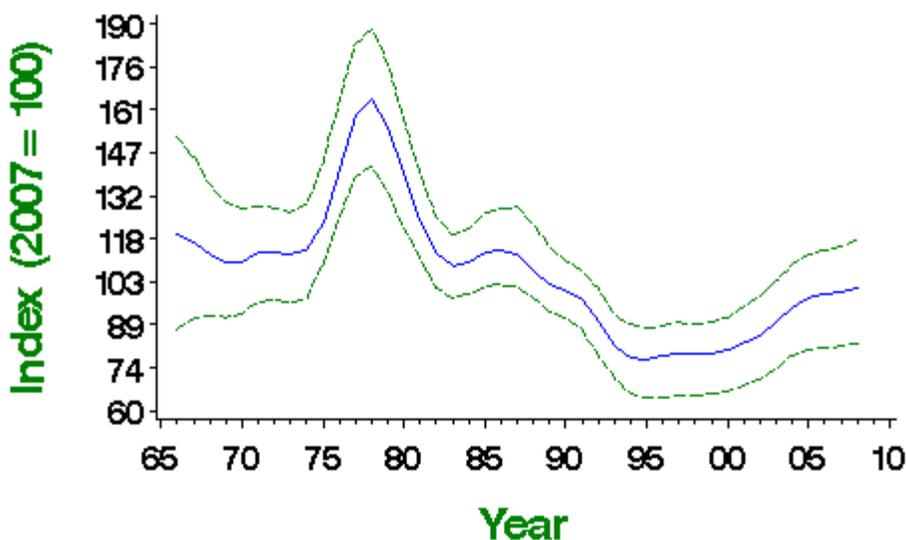

### Status summary

Since Red-legged Partridge is a non-native species released in the UK for the purpose of being shot by hunters, its possible population decrease over the recent 25-year period raises no conservation concern. Moreover, BBS data indicate that significant increase has occurred in the UK since 1994. [Game-bag data](#) show that the numbers released per unit area onto shooting estates, and the numbers shot, have both increased more than eightfold since 1980: around 6.5 million birds have been released annually in the UK in recent years ([PACEC 2006](#)). The effects on native fauna of such vast-scale releases of this species and [Pheasant](#) have been little studied. There is now evidence, however, that shooting operations based on large-scale releases of Red-legged Partridges can lead to local extinction of the red-listed native [Grey Partridge](#) ([Watson et al. 2007](#)).

**GREY PARTRIDGE***Perdix perdix*

• Population changes

• Productivity trends

• Additional information

**Conservation listings**

Europe: SPEC category 3 (vulnerable)

UK: red (&gt;50% population decline)

UK Biodiversity Action Plan: [click here](#)**Long-term trend**

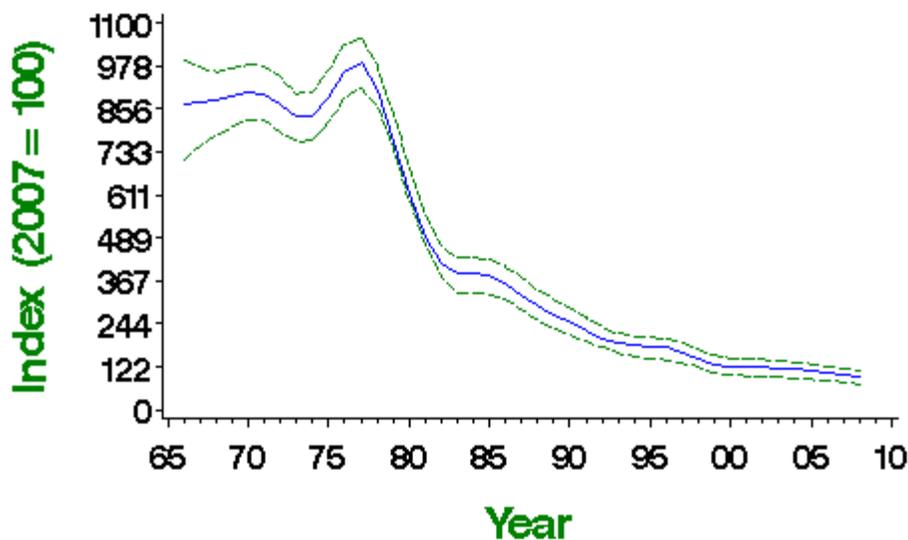

UK, England: rapid decline

**UK population size**70,000–75,000 pairs in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))**Status summary**

This species has declined enormously, probably because of the effects of agricultural intensification (specifically herbicides) on the food plants of young chicks' insect prey ([Potts 1986](#)). Despite years of research and the application of a government Biodiversity Action Plan ([Aebischer & Ewald 2004](#)), the continuing decline shown by CBC/BBS suggests that all efforts to boost the population have so far been unsuccessful. Local extinctions are now likely to be widespread, but masked in some areas by continuing releases of hand-reared birds onto shooting estates. Artificial rearing has increased since the mid 1980s, despite the failure of restocking as a means of restoring breeding numbers (see [here](#)), while releases of non-native gamebirds, which have increased greatly, can be detrimental to the native species. Infection with caecal nematodes from farm-reared [Pheasants](#) may be contributing to the decline of Grey Partridges in Britain ([Tompkins et al. 2002](#)). The practice of releasing [Red-legged Partridges](#) in large numbers can lead to Grey Partridge extinction, in part because shooters are unable to distinguish these two species ([Watson et al. 2007](#)): these authors conclude that overshooting has greater implications for Grey Partridge conservation than raptor predation. Grey Partridge is one of the most strongly decreasing bird species in Europe, with rapid declines evident in all regions ([PECBMS 2009](#)).

## RED-THROATED DIVER

### *Gavia stellata*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: SPEC category 3 (depleted)

UK: amber (European status)

### Long-term trend

UK: increase

### UK population size

935–1,500 pairs in 1994 ([Gibbons et al. 1997: BiE04, APEP06](#)); 1,255 (1,014–1,551) pairs in 2006 ([Dillon et al. 2009](#))

### Status summary

Population trends are not monitored by the BTO, but JNCC's [Seabird Monitoring Programme](#) shows that breeding numbers at sample study areas in Shetland fluctuated without long-term change during 1980–2005, with low points in 1980, 2000 and 2004 ([Mavor et al. 2008](#)). Complete surveys of Shetland indicated a decrease of 36% there between 1983 and 1994, however ([Gibbons et al. 1997](#)). The estimated breeding population in 2006 had increased significantly by 34% since the first national survey in 1994, with stability in Shetland and Orkney but increase across the Hebrides and Scottish mainland ([Dillon et al. 2009](#)). Since the 1980s, there may have been some tendency for more pairs to hatch a second chick, although two-chick broods are only occasional in Orkney and the proportion of nest records from there could have changed over time.

### Population changes in detail

Annual breeding population changes are not currently monitored by BTO for this species

## LITTLE GREBE

*Tachybaptus ruficollis*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: amber (25–50% population decline)

### Long-term trend

UK: uncertain

### UK population size

5,900–12,000 pairs in 1990 (1988–91 Atlas: [APEP06](#)); 3,800–13,000 pairs in 2000 (updated using CBC and WBS trends: [BiE04](#))

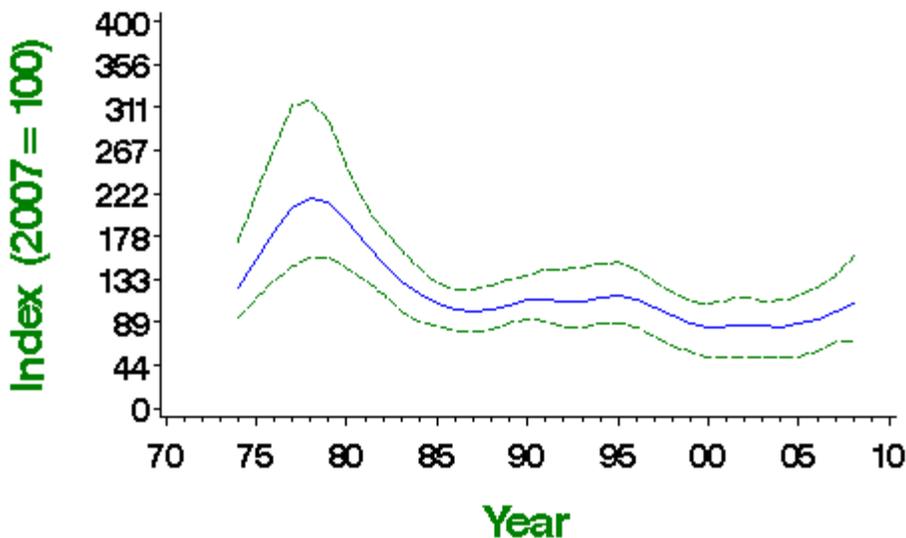

### Status summary

The rapid decline shown by the WBS/WBBS may reveal problems among birds on linear waterways during the early 1980s and since the late 1990s, while shallow increases shown by the CBC and by BBS may suggest that wider populations (including birds on small still waters) are healthy. Because of the shortage of data, and the conflict between WBS and BBS assessments, the rapid decline indicated by WBS in the 1980s did not initially trigger a conservation listing. The species was moved from the green to the amber list in 2009, however, on the strength of its UK decline. In an analysis of nest record cards, [Moss & Moss \(1993\)](#) found that nests on ponds and lakes were significantly more successful than those on rivers and streams and that nests on rivers, subject to fluctuating water levels, experienced significantly higher failure rates through flooding than those on canals, where water levels are artificially maintained. Winter numbers, monitored by [WeBS](#), have shown sustained shallow increase ([Holt et al. 2009](#)).

## GREAT CRESTED GREBE

### *Podiceps cristatus*

- Population changes
- Productivity trends
- Additional information

#### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: green

#### Long-term trend

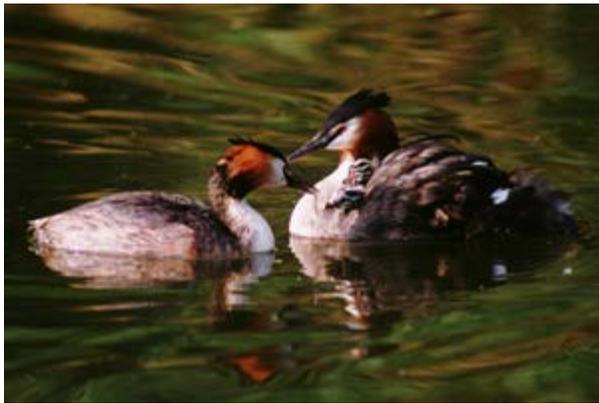

UK: probable increase

#### UK population size

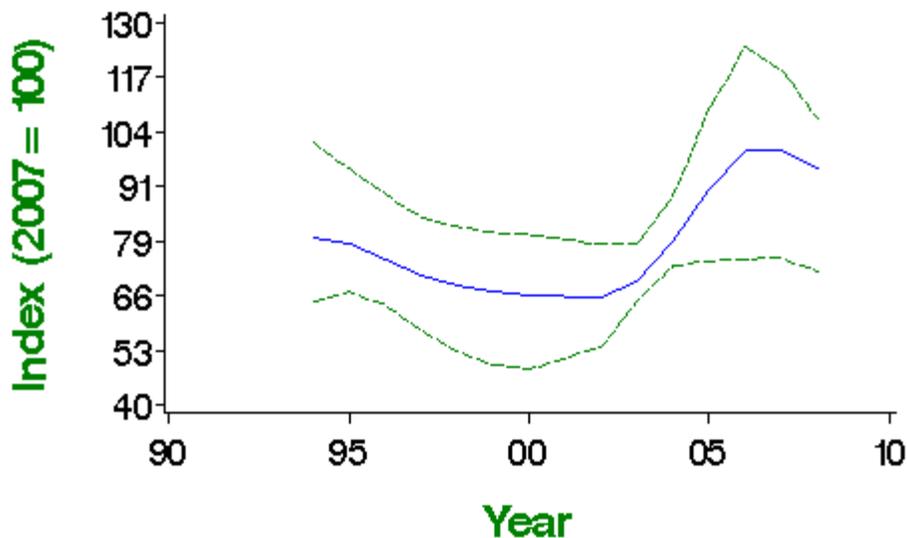

9,400 adults in 1990 (1988–91 Atlas: [APEP06](#)); 6,100 pairs in 2000 (updated using BBS trend: [BiE04](#))

#### Status summary

This species was believed to be on the verge of extinction in Britain around 1860, when only 32–72 pairs were known in England ([Holloway 1996](#)). A subsequent increase followed reductions in persecution, aided by statutory protection, and the creation of habitat in the form of gravel pits ([Gibbons et al. 1993](#)). Increase was tracked by special surveys to around 7,000 adult birds in Britain by 1975 ([Hughes et al. 1979](#)). The BBS provides the first annual, national monitoring of this species and indicates shallow increase since 1994. Winter numbers, monitored by [WeBS](#), have shown sustained shallow increase ([Holt et al. 2009](#)).

**CORMORANT***Phalacrocorax carbo*

• Population changes

• Productivity trends

• Additional information

**Conservation listings**

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: green (species level); amber (race *carbo*, >20% of European breeders; race *sinensis*, localised breeding)

**Long-term trend**

UK: increase

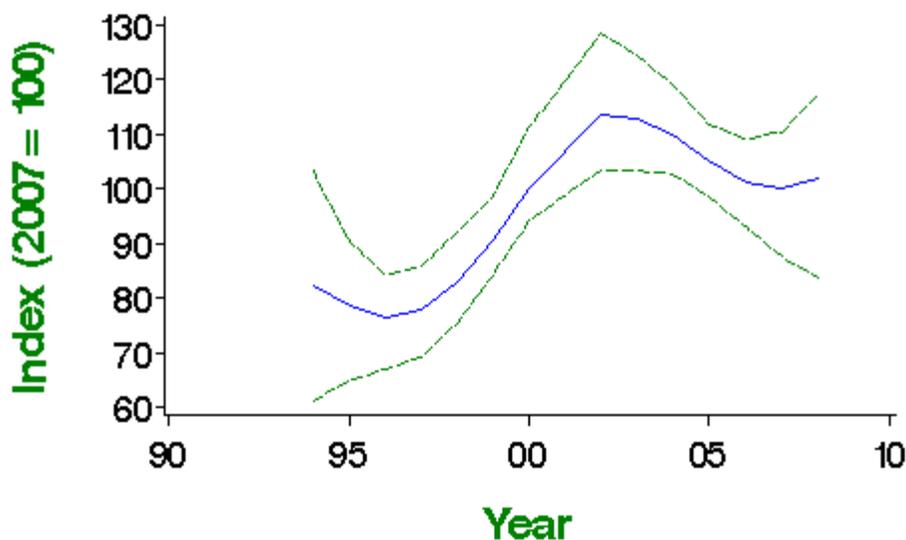

**UK population size**

9,018 pairs in 1998–2002 ([Mitchell et al. 2004: APEP06](#));

9,100 pairs including Channel Islands ([BiE04](#))

**Status summary**

The Cormorant was almost exclusively a coastal breeder in the UK until 1981, but has since established colonies in many inland areas of eastern and central England ([Rehfisch et al. 1999](#); [Newson et al. 2006](#)). Breeding numbers and productivity at sample colonies have been monitored annually since 1986 by JNCC's **Seabird Monitoring Programme**. Overall in Britain and Ireland there was a 15% increase in the population between full surveys in 1985–88 and 1998–2002 ([Mitchell et al. 2004](#)). Trends during 1986–2005 show decreases in Scotland and in northeast and southwest England, but no trend in Wales, and steep increases inland in England and in regions bordering the northern part of the Irish Sea ([Mavor et al. 2008](#)). By 2005, breeding had been recorded at 58 inland sites, and the inland population had risen to about 2,130 pairs ([Newson et al. 2007](#)). Inland breeding in England is thought to have been sparked by birds of the continental race *sinensis* from the Netherlands and Denmark, although many nominate *carbo* from coastal colonies in Wales and England have contributed to its development. The winter trend in Britain, comprising British and Irish breeders and continental visitors, has shown strong increase since the late 1980s but now appears more stable ([Holt et al. 2009](#)). Although the species is now green listed, both races that occur in the UK warrant amber listing, for reasons unconnected with the UK trend.

## GREY HERON

*Ardea cinerea*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: green

### Long-term trend

UK, England: moderate increase

Wales, Scotland: shallow increase

### UK population size

14,200 nests in 2003 (Heronries Survey 2003: [APEP06](#));

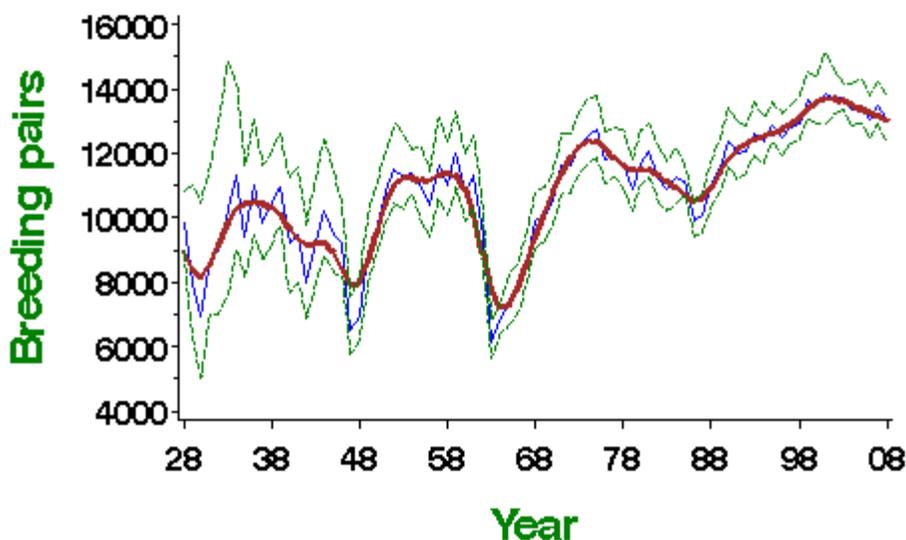

12,959 (12,358–13,795) nests in 2008 (Heronries Census)

### Status summary

The [BTO Heronries Census](#), which has monitored Grey Herons since 1928, shows the species to be more abundant in the early 2000s than at any time in the last 80 years. The effects of harsh winters, which induce severe mortality in this species ([Besbeas et al. 2002](#)), are clearly visible in the long-term trend. The general increase that underlies these fluctuations may stem from reduced persecution, improvements in water quality, the provision of new habitat as new lakes and gravel pits mature, and increased feeding opportunities at freshwater fisheries ([Gibbons et al. 1993](#), [Marchant et al. 2004](#)). A downturn evident since 2001 seems unrelated to winter weather and is, as yet, unexplained. High rates of nest failure at the chick stage were noted in the late 1960s, but not subsequently. The mean laying date has advanced by almost a month since 1968. In the latest [special survey of UK heronries](#), carried out in 2003 to mark the 75th anniversary of the Heronries Census, a record total of more than 10,441 Grey Heron nests were counted. The current population estimates for that year, implying that around 3,300 nests in the UK were not reported to the survey, allow for known heronries (mostly in Scotland) that were not visited in 2003, but not for the few areas, mainly in Scotland and Northern Ireland, where heronries have never been counted. This issue was addressed by random tetrad searches conducted in 2003 and 2004. Numbers have risen widely across Europe since 1980 ([PECBMS 2009](#)).

**HEN HARRIER***Circus cyaneus*

• Population changes

• Productivity trends

• Additional information

**Conservation listings**

Europe: SPEC category 3, vulnerable

UK: red (historical decline)

**Long-term trend**

UK: probable increase

**UK population size**

570 (500–640) territorial pairs in 1998 ([Sim et al. 2001](#): [BiE04](#), [APEP06](#)); 806 (732–889) territorial pairs in 2004 ([Sim et al. 2007a](#))

**Status summary**

Red listed because of substantial declines over the last two centuries, this species has suffered in recent decades from loss of habitat as forestry plantations have matured ([Bibby & Etheridge 1993](#)) but more especially from continuing illegal persecution ([Etheridge et al. 1997](#)). Although the Hen Harrier and other raptors have been protected under UK law since 1961, many are still unlawfully killed or disturbed in efforts to protect the economic viability of driven shooting of **Red Grouse** ([Thompson et al. 2009](#)). The UK population was unchanged between surveys in 1988–89 and 1998, with declines in Orkney and England but increases in Northern Ireland and the Isle of Man ([Sim et al. 2001](#)). A decrease of 70% in the Orkney population over the last 20 years has been linked to reductions in the area of unmanaged grassland ([Amar & Redpath 2005](#)); the demographic drivers of this decline have been a decrease in polygyny and reduced nesting success among secondary females ([Amar et al. 2005](#)). The latest survey reveals a 41% increase in the UK and Isle of Man during 1998–2004, but with decreases in the Southern Uplands, east Highlands and England, all being areas with many managed grouse moors ([Sim et al. 2007a](#)). Although average clutch size declined substantially during the 1980s, further investigation has shown that this trend is due to the increased proportions in recent years of records from Orkney, where clutch sizes tend to be smaller than on the mainland ([Summers 1998](#), [Crick 1998](#)). Recent results confirm that rough grass is a critical habitat for Orkney Hen Harriers, providing the necessary food during the incubation period ([Amar et al. 2008](#)).

**Population changes in detail**

Annual breeding population changes for this species are not currently monitored by BTO

## SPARROWHAWK

*Accipiter nisus*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: green

### Long-term trend

England: rapid increase

### UK population size

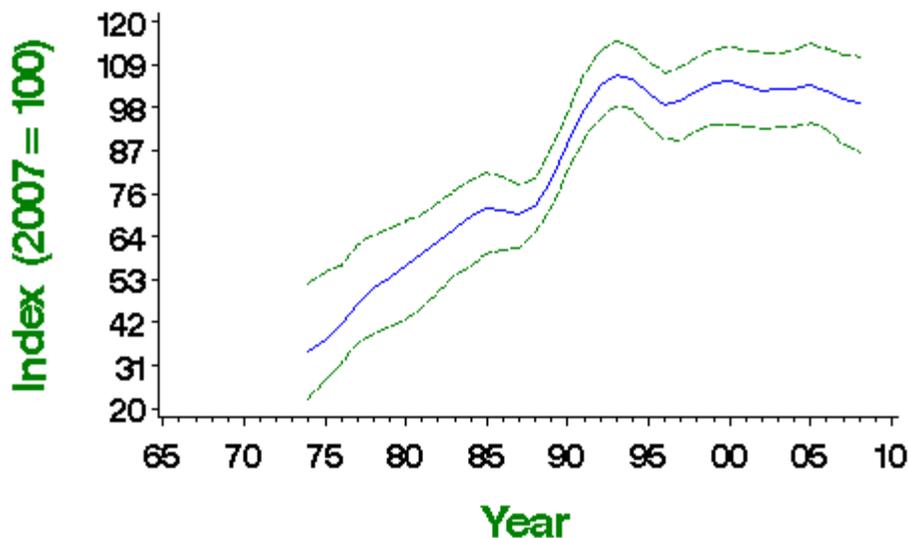

40,100 pairs in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

### Status summary

Sparrowhawks suffered a severe population crash caused by organochlorine pesticides in the 1950s and 1960s, when the species was extinguished from large areas of lowland Britain ([Newton 1986](#)). Following a ban on the use of organochlorines, the species increased and spread, and became common enough on CBC plots for annual monitoring in the early 1970s. Between then and the mid 1990s, the CBC charted a steep increase. Many former haunts especially in the Midlands and east of England were reoccupied between the two atlas periods ([Gibbons et al. 1993](#)). Improving numbers of fledglings per breeding attempt is likely to have contributed to this remarkable period of success: failure rates at the egg stage fell markedly from high initial values, and brood sizes increased throughout. The population has stabilised since the mid 1990s and, possibly through the effects of intraspecific competition, average brood size has begun to fall again.

### CBC/BBS England 1974–2008 Sparrowhawk

## BUZZARD

*Buteo buteo*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: green

### Long-term trend

UK, England: rapid increase

### UK population size

31,100–44,000 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#)); 44,000–61,000 territorial pairs in GB in 2001 ([Clements 2002](#))

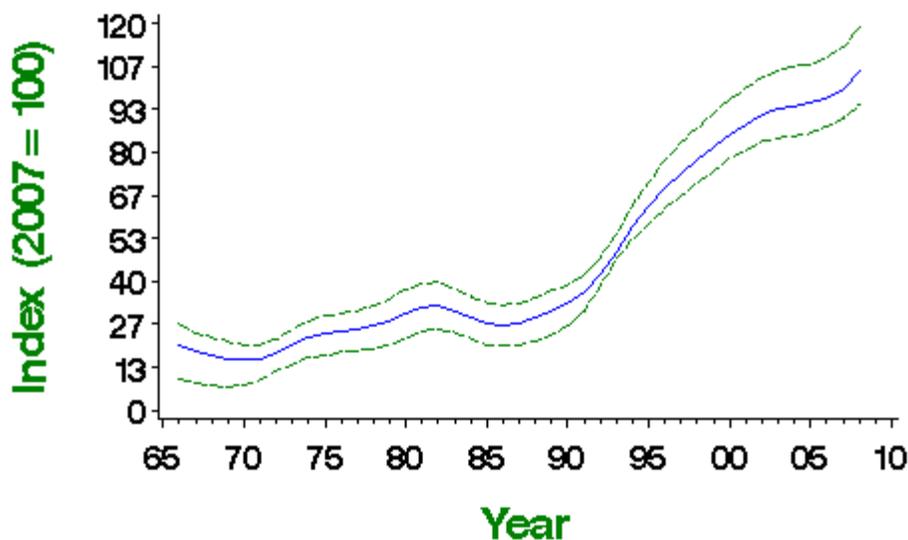

### Status summary

The Common Buzzard has shown a substantial eastward range expansion since the 1988–91 Atlas, and is arguably now the most abundant diurnal raptor in Britain ([Clements 2002](#)). The increasing trend identified by the CBC relates especially to the spread of range into central and eastern Britain, where CBC was more strongly represented. If anything, however, the upsurge has been amplified with the addition of the more geographically representative BBS data since 1994. The increase has been associated with rapidly improving nesting success, perhaps through reduced persecution, the recovery of rabbit populations from the effects of myxomatosis and release from the deleterious effects of organochlorine pesticides ([Elliott & Avery 1991](#), [Clements 2002](#)).

## KESTREL

*Falco tinnunculus*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: SPEC category 3, declining

UK: amber (25–50% population decline)

### Long-term trend

England: fluctuating, with no long-term trend

### UK population size

36,800 pairs in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

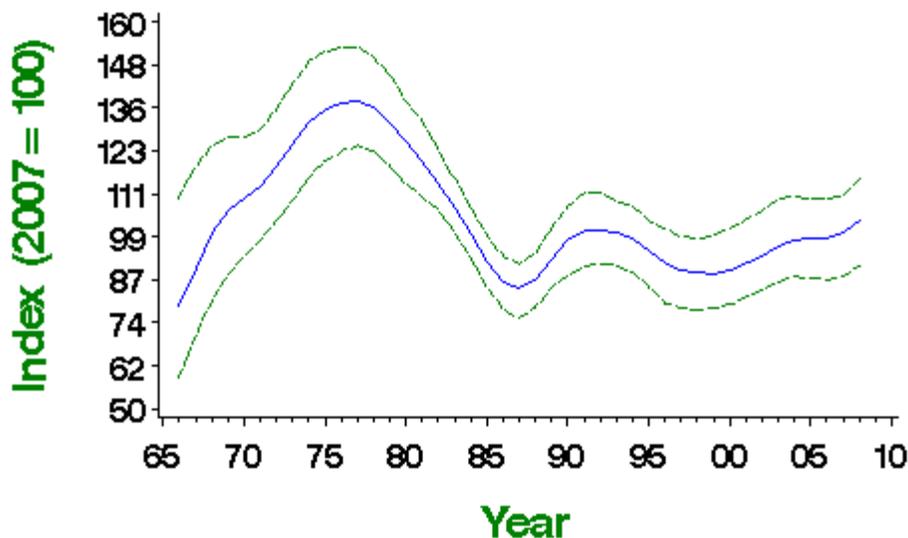

### Status summary

Kestrels had recovered from the lethal and sublethal effects of organochlorine pesticides by the mid 1970s, the recovery probably driven by improving nesting success, but subsequently entered a decline which has been linked to the effects of agricultural intensification on farmland habitats and their populations of small mammals ([Gibbons et al. 1993](#)). Since the mid 1980s, the English population has fluctuated without a long-term trend being apparent. In Scotland, however, there has been a significant decline since 1994. There has been substantial increase in the number of fledglings per breeding attempt; brood sizes increased up to 1990, but a subsequent decline has resulted in the inclusion of Kestrel in the NRS concern list ([Leech & Barimore 2008](#)). Despite its decline since the mid 1970s, the Kestrel breeds at high density in mixed farmland across much of England, suggesting that the British population may number more than 50,000 pairs ([Clements 2008](#)).

**MERLIN*****Falco columbarius***

- Population changes

- Productivity trends

- Additional information

**Conservation listings**

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: amber (historical decline)

**Long-term trend**

UK: probable increase

**UK population size**

1,300 pairs in 1990–94 ([Rebecca & Bainbridge 1998](#): [BiE04](#), [APEP06](#))

**Status summary**

Having declined substantially over the past two centuries, Merlin shows indications of a recent doubling of population ([Rebecca & Bainbridge 1998](#)). This increase may be associated with an increased use of forest edge as a nesting habitat ([Parr 1994](#), [Little et al. 1995](#)). Because of its recent population upturn, the species was moved from the red to the amber list in 2002. It remains much too scarce, however, for annual population monitoring via BBS: dedicated observers and specialised field methods are required, as described by [Hardey et al. \(2009\)](#). Submissions to the Rare Breeding Birds Panel fall well short of the estimated UK total population but show an average of 1.86 young fledged per occupied territory during 1996–2004 ([Holling & RBBP 2007a](#)). Breeding performance has tended to improve since the 1960s, probably linked to the declining influence of organochlorine pesticides ([Crick 1993](#)). Hatching rates in the southeast Yorkshire Dales were consistently higher than had been recorded in earlier studies in Northumberland ([Wright 2005](#)). A repeat survey of Merlin's British breeding status was undertaken in 2008.

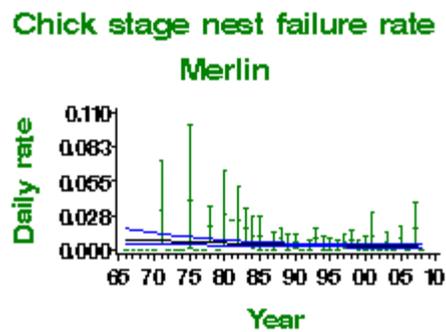

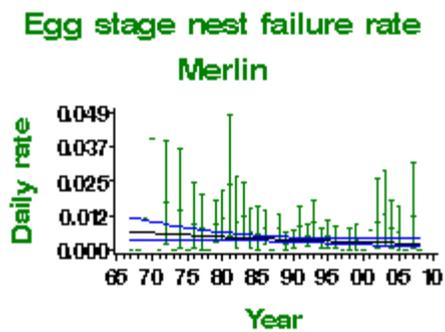

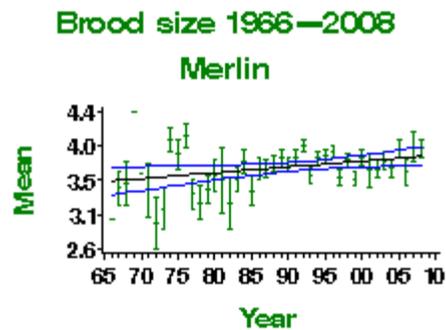

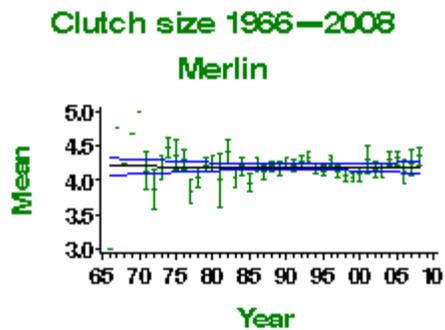

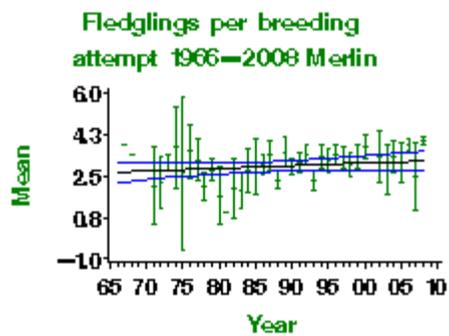

**Population changes in detail**

## HOBBY

### *Falco subbuteo*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: green

### Long-term trend

UK: increase

### UK population size

2,200 pairs in 2000 ([Clements 2001](#): [BiE04](#), [APEP06](#))

### Status summary

This species cannot be monitored by any of the standard monitoring schemes, due to its low population density and unobtrusive habits. Many sightings must refer to migrants, first-summer non-breeders, or to breeding birds from distant nests, and do not help to establish whether nesting occurs in the locality. Dedicated observers and specialised field methods are required, as described by [Hardey \*et al.\* \(2009\)](#). The Rare Breeding Birds Panel collects annual data, which under-represent the true population to unknown degrees, but adequately establish the long-term upward trend ([Holling & RBBP 2010](#)). The Hobby's distribution has spread markedly northwards in England since the 1970s ([Gibbons \*et al.\* 1993](#)), perhaps linked to increases in its dragonfly prey supplies ([Prince & Clarke 1993](#)) and to a decreasing dependency on its traditional heathland habitat, but the reasons underlying the increase are still only speculative ([Clements 2001](#)). A success rate of more than 90% was recorded for nests in Derbyshire during 1992–2001, with successful nests fledging a mean of 2.44 young ([Messenger & Roome 2007](#)). The small annual samples of nest record cards indicate no long-term change in either brood size or nest success.

### Population changes in detail

## PEREGRINE

### *Falco peregrinus*

- Population changes

- Productivity trends

- Additional information

### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: green (species level); amber (race *peregrinus*, >20% of European breeders, European status)

### Long-term trend

UK, England: increase

Northwest Scotland: decline since 1991

### UK population size

1,283 pairs in 1991 ([Crick & Ratcliffe 1995: APEP06](#));

1,400 pairs in 2002 ([Banks et al. 2003: BiE04](#))

### Status summary

The UK population size, distribution and breeding performance have all largely recovered from the detrimental effects of organochlorine pesticides in the 1950s and 1960s. Populations and breeding performance have declined recently, however, in northwest Scotland and the Northern Isles ([Crick & Ratcliffe 1995](#)). Nest record information for the UK as a whole shows a significant decline in clutch size, although samples for the first ten years are small. No trends are yet evident in the number of fledglings per breeding attempt. The number of UK breeding pairs has been censused every ten years since 1961 by BTO/JNCC/RSPB/Raptor Study Groups, and has been estimated as follows: 1961 – 385 pairs; 1971 – 489 pairs; 1981 – 728 pairs; 1991 – 1,283 pairs ([Ratcliffe 1993](#)). The [National Peregrine Survey 2002](#) found 1,402 breeding pairs, a further 10% increase overall since 1991 but with declines in north and west Scotland, North Wales and Northern Ireland ([Banks et al. 2003](#)); around 50 pairs were missed in Wales, however ([Dixon et al. 2008](#)). Similar increases across Europe have resulted in a downgrading of conservation listing from 'SPEC 3 (rare)' to 'secure' ([BirdLife International 2004](#)), and consequently the species has recently been moved from the amber to the green list in the UK.

### Population changes in detail

## MOORHEN

### *Gallinula chloropus*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: green

### Long-term trend

UK: fluctuating, with no long-term trend

### UK population size

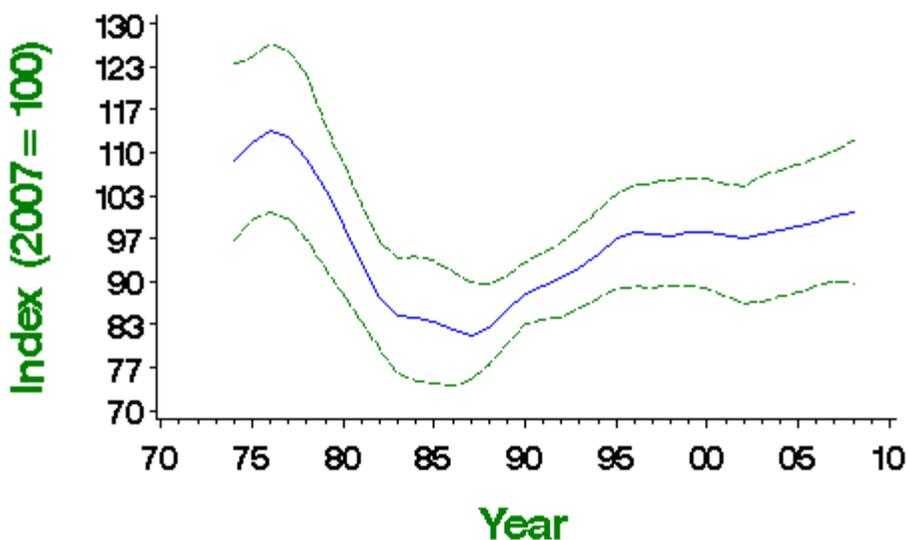

270,000 pairs in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

### Status summary

While the long-term CBC/BBS trend is of shallow increase, much of the population increase took place before 1974, when WBS monitoring began, and may have been a recovery from heavy mortality during the cold winters of the early 1960s. On both CBC/BBS and WBS/WBBS evidence, there was decrease during the 1970s and 1980s, but this has been followed by a partial recovery. A decline in the number and quality of farmland ponds, and the spread of American mink *Mustela vison*, which is an important predator especially along watercourses, have been suggested as possible causes of decline. The failure rate of nests over the full 25-day egg period (20 days for incubation and 5 days for laying) has increased, earning the species a place on the NRS concern list ([Leech & Barimore 2008](#)), but average brood sizes have increased and no trend has been evident in the number of fledglings per breeding attempt.

## COOT *Fulica atra*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: green

### Long-term trend

UK waterways: rapid increase

### UK population size

22,600–28,800 pairs in 2000 (1988–91 Atlas estimate updated using CBC/BBS and WBS trends: [BiE04](#), [APEP06](#))

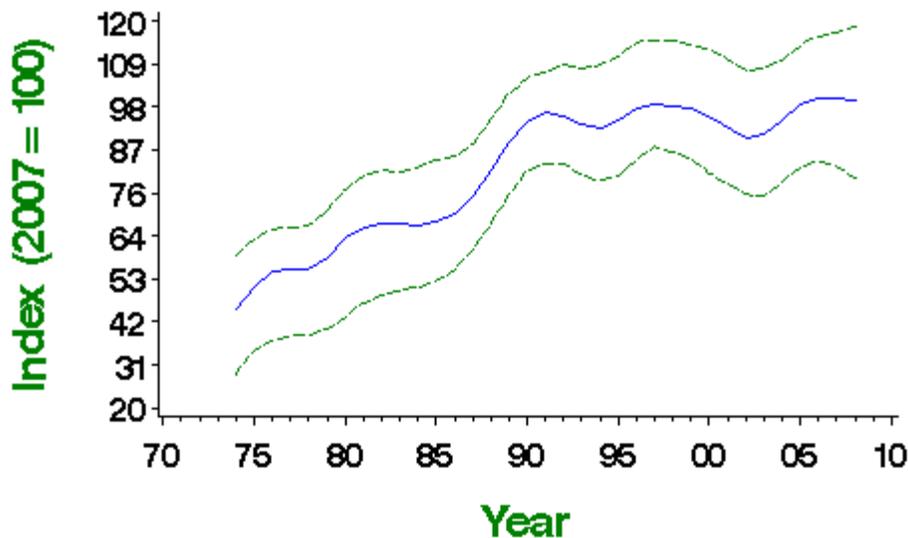

### Status summary

WBS/WBBS and CBC/BBS trends for Coot indicate a long-term increase, although the magnitude of the change is not clear. Small CBC samples, mainly of birds on small water-bodies, suggested a rapid rise in the late 1960s. WBS/WBBS and BBS include more birds on larger waters, and so may be more representative of Coot populations, but WBS/WBBS has not recorded the strong increase found by BBS observers since 1994. The combination of CBC and BBS data suggests that the long-term increase in the UK and England may have been rapid. Winter abundance on large still waters, as monitored by WeBS, showed shallow increase from the mid 1980s to around 2000/01 but has since declined, especially in Northern Ireland ([Holt et al. 2009](#)).

## OYSTERCATCHER

*Haematopus ostralegus*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (concentrated in Europe, conservation status favourable)

UK: amber (>20% of European breeding population, >20% of East Atlantic Flyway population in winter, localised wintering population)

### Long-term trend

UK waterways: moderate increase

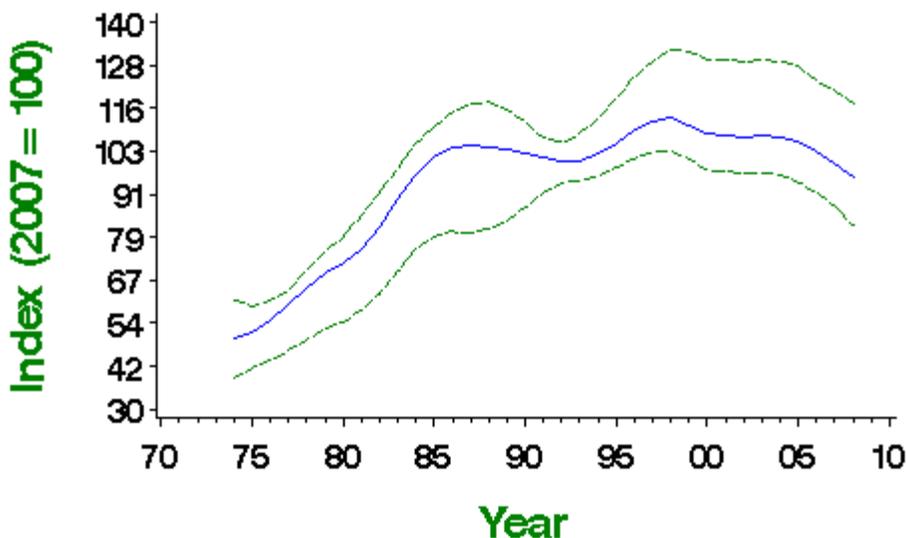

### UK population size

113,000 (98,500–127,000) pairs in 1985–99 (O'Brien 2005: BiE04, APEP06)

### Status summary

Oystercatchers increased along linear waterways between 1974 and about 1986, as the species colonised inland sites across England and Wales (Gibbons *et al.* 1993). Thereafter, the WBS index stabilised, so showing a pattern similar to that in winter abundance revealed by WeBS (Holt *et al.* 2009). Surveys in England and Wales revealed an increase of 47% in breeding birds in wet meadows between 1982 and 2002 (Wilson *et al.* 2005). BBS data since 1994, which include birds in a broader range of locations and habitats, show strong increase in England but a significant decline in Scotland. The increase in nest failure rates during the 27-day egg stage (25 days for incubation and 2 days for laying) probably results from the spread of the species into less favourable habitats, where nest losses through predation or trampling may be more likely. The trend towards earlier laying can be partly explained by recent climate change (Crick & Sparks 1999).

### WBS/WBBS 1974–2008 Oystercatcher

1975-2007: 92% (confidence interval 44% to 199%)

**RINGED PLOVER***Charadrius hiaticula*

• Population changes

• Productivity trends

• Additional information

**Conservation listings**

Europe: no SPEC category (concentrated in Europe, conservation status favourable)

UK: amber (species level and race *hiaticula*, 25–50% decline, >20% East Atlantic Flyway population in winter)

**Long-term trend**

UK: decline

**UK population size**

8,540 pairs in 1984 (Prater 1989: APEP06, rounded to 8,600 BiE04); 5,438 (5,257–5,622) pairs in 2007 (Conway *et al.* 2008)

**Status summary**

The breeding population is not monitored annually, but a BTO survey in 1984 showed increases throughout the UK since the previous survey in 1973–74 (Prater 1989). The spread of the breeding distribution inland between the two atlas periods, especially in England, was probably associated with the increase in number of gravel pits and reservoirs (Gibbons *et al.* 1993). The 1984 survey revealed that over 25% of the UK population nested on the Western Isles, especially on the machair, but breeding waders there have subsequently suffered greatly from predation by introduced hedgehogs (Jackson *et al.* 2004) – a problem that appears increasingly severe (Jackson 2007). Surveys in England and Wales revealed an increase of 12% in breeding birds in wet meadows between 1982 and 2002 (Wilson *et al.* 2005). The BTO's repeat national survey in 2007 found an overall decrease in UK population of around 37% since 1984, with the greatest decreases in inland areas (Burton & Conway 2008, Conway *et al.* 2008, Conway & Burton 2009; click [here](#)). Ringed Plovers that choose beaches for nesting are especially vulnerable to disturbance, however, and already in 1984 were largely confined in some regions to wardened reserves (Prater 1989). Human usage of beach areas severely restricts the availability of this habitat to nesting plovers (Liley & Sutherland 2007). The marked increase in nest failures at the egg stage has earned Ringed Plover a place on the NRS concern list (Leech & Barimore 2008). Wintering numbers have been in decline since the late 1980s (Holt *et al.* 2009).

**Population changes in detail**

## GOLDEN PLOVER

*Pluvialis apricaria*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (concentrated in Europe, conservation status favourable)

UK: amber

### Long-term trend

UK: possible decline

### UK population size

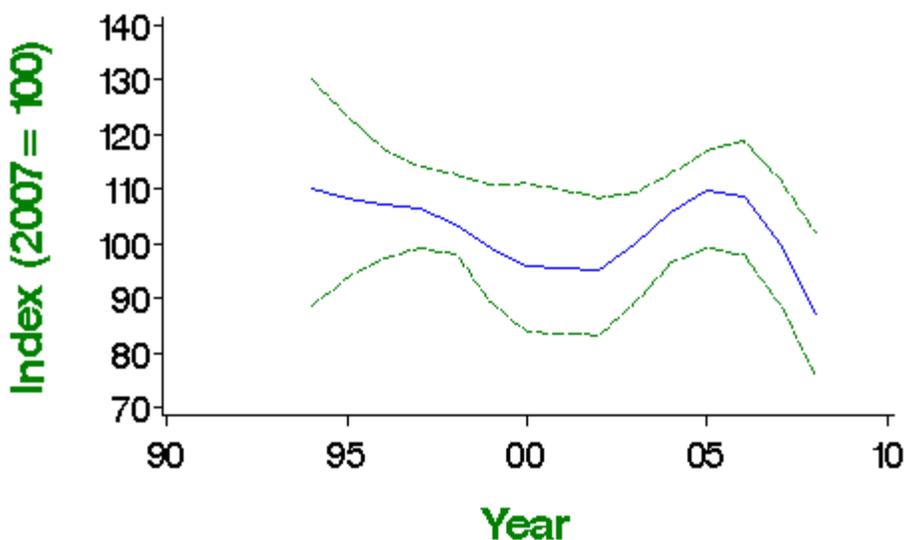

22,600 pairs in 1981–84 (Reed 1985, Stroud *et al.* 1987: APEP06); 38,400–59,400 pairs in 1980–2000 (BiE04)

### Status summary

There was no annual monitoring of the breeding population before the inception of BBS. Since 1994, BBS has shown some increase in Scotland and the UK, but this is believed to follow an earlier decline (Gibbons *et al.* 1993). A detailed survey has confirmed a sharp decline in Wales since the 1980s, with just 36 pairs located in 2007 (Johnstone *et al.* 2008). Nest survival on grass moors, unlike that on heather moors, may have declined over time (Crick 1992), perhaps linked to increased stocking densities of sheep (Fuller 1996). There is no clear trend in clutch size; a large number of late-season nest records, which provide higher proportions of two- and three-egg clutches, were submitted from an intensive study during 1996–98 (J.W. Pearce-Higgins, pers. comm.). Warmer springs are reported to advance the breeding phenology of Golden Plovers and of their tipulid prey (Pearce-Higgins *et al.* 2005). Winter numbers counted by WeBS, although mainly at coastal sites and omitting some big concentrations inland, have increased sharply in Britain since the mid 1980s (Holt *et al.* 2009); these birds are mainly of Fennoscandian or Russian origin. The species has recently been restored to the amber list because of the international importance of the UK's wintering population.

**LAPWING***Vanellus vanellus*

• Population changes

• Productivity trends

• Additional information

**Conservation listings**

Europe: SPEC category 2, vulnerable

UK: red

UK Biodiversity Action Plan: priority species

**Long-term trend**

UK: moderate decline

**UK population size**156,000 (137,000–174,000) pairs in 1985–99 ([O'Brien 2005](#): [BiE04](#), [APEP06](#))**Status summary**

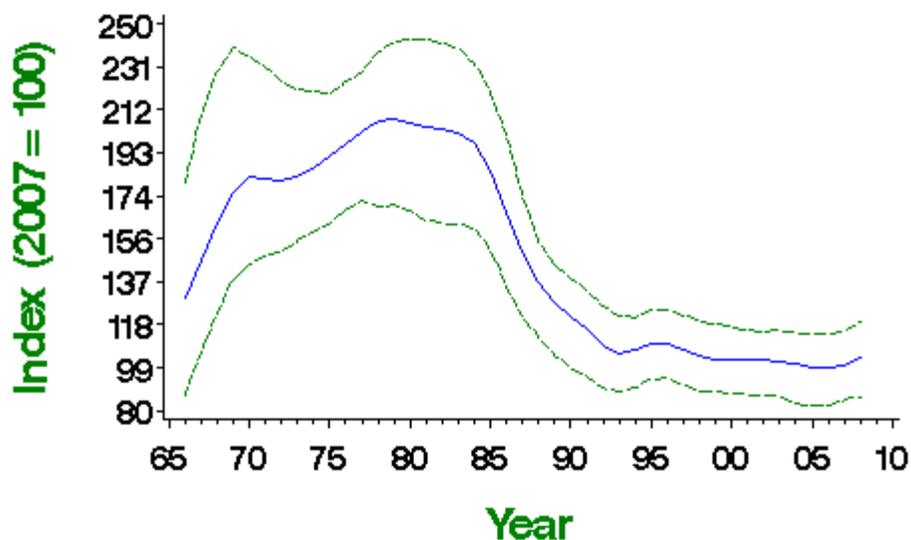

Although CBC recorded some increase in its early years, Lapwings have declined continuously on lowland farmland since the mid 1980s, probably because changes in agricultural practice have led to their breeding productivity dropping below a sustainable level ([Galbraith 1988](#), [Hudson \*et al.\* 1994](#), [Siriwardena \*et al.\* 2000a](#), [Besbeas \*et al.\* 2002](#), [Milsom 2005](#)). National surveys in England and Wales showed a 49% population decline between 1987 and 1998 ([Wilson \*et al.\* 2001](#)). Population declines of more than 50% over 15 years in Northern Ireland ([Henderson \*et al.\* 2002](#)) mirror similar declines throughout grassland areas of Wales and southeast England ([Wilson \*et al.\* 2001, 2005](#)). BBS data indicate some increase in England since 1994, but steep decline in Scotland. Adult and first-year survival rates show no trend through time ([Peach \*et al.\* 1994](#), [Catchpole \*et al.\* 1999](#)). Mean clutch size increased significantly as the population fell. Using NRS data for 1962–99, [Chamberlain & Crick \(2003\)](#) found that marginal upland had relatively low reproductive performance, and arable relatively high, while grazed grass had higher failure rates and lower clutch sizes than ungrazed grass: their results suggest that recent population change may have been influenced by changes in clutch failure rates, perhaps mediated by an increase in grazing intensity in marginal uplands and by increased predation, possibly associated with habitat change. There have been several very poor years for egg-stage survival since 1996, and the species is therefore now of NRS concern ([Leech & Barimore 2008](#)). A recent study has indicated that 88% of nest predations occurred during darkness, suggesting that nocturnal mammals were to blame ([Bolton \*et al.\* 2007](#)). Nests with close neighbours and furthest from field edges were most likely to survive ([MacDonald & Bolton 2008](#)). [Sharpe \*et al.\* \(2008\)](#), however, conclude that chick mortality is the main determinant of poor Lapwing productivity and therefore of population decline.

Winter numbers counted by WeBS, mainly at coastal sites and omitting some big concentrations inland, increased in Britain during the 1980s and early 1990s and are now decreasing again ([Holt \*et al.\* 2009](#)); these birds are mainly of continental origin. Lapwing is one of the most strongly declining bird species in Europe, having decreased in all regions since 1980, although with differing regional timing ([PECBMS 2009](#)). The 2009 review moved this species from amber to the UK red list, for which it qualifies on the strength of its UK decline.

## SNIPE

### *Gallinago gallinago*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: SPEC category 3 (declining)

UK: amber (European status)

### Long-term trend

UK: probable decline

### UK population size

59,300 (52,600–69,000) pairs in 1985–99 (O'Brien

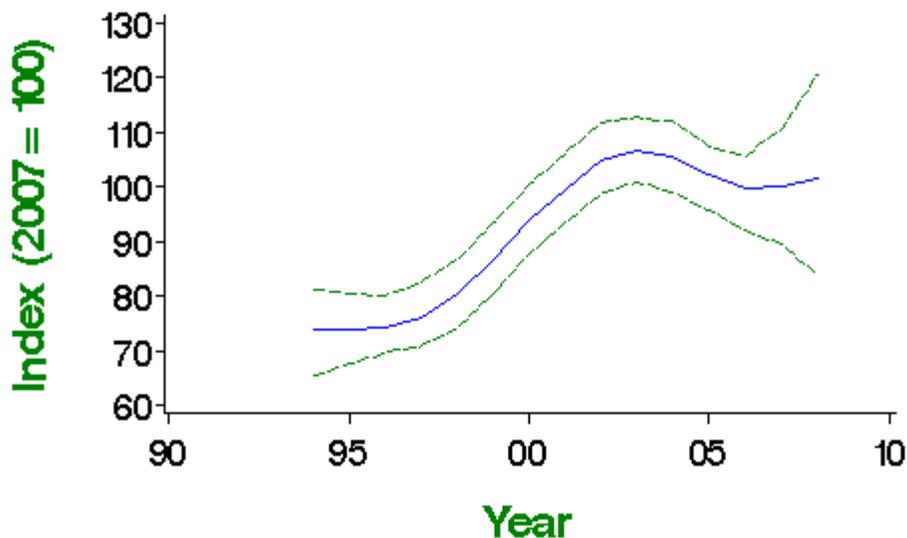

2005: [BiE04](#), [APEP06](#))

### Status summary

Snipe were monitored by the CBC mainly in lowland England, where numbers have fallen rapidly since the 1970s as farmland has been drained (Gibbons *et al.* 1993, Siriwardena *et al.* 2000a). The CBC index fell from the early 1970s until 1984, when the number of occupied plots became too small for further monitoring (Marchant *et al.* 1990), and the graph is not shown here. In Northern Ireland, a breeding decline of around 30% occurred between the mid 1980s and 1999 (Henderson *et al.* 2002). Surveys in England and Wales revealed a decrease of 62% in breeding birds in wet meadows between 1982 and 2002, with the remaining birds becoming highly aggregated into a tiny number of suitable sites (Wilson *et al.* 2005). Birds were more likely to persist where soils remained soft and wet; the fact that Snipe have continued to decline, despite soil conditions being improved for them at many lowland wetland reserves, suggests that other key aspects of habitat quality, such as prey abundance, are more likely to be driving the decline (Smart *et al.* 2008). The trend in the upland and moorland strongholds of the species is not fully known, but the 1988–91 atlas documented range loss widely in Wales, Northern Ireland and Scotland, as well as lowland England, and a general decrease is therefore highly probable. The BBS shows increases in England and especially in Scotland since 1994, though with little change in recent seasons. Daily nest failure rates at the egg stage appear to have halved. Following declines across much of Europe since 1980 (PECBMS 2009), this previously 'secure' species is now provisionally evaluated as 'declining' (BirdLife International 2004).

**WOODCOCK***Scolopax rusticola*

• Population changes

• Productivity trends

• Additional information

**Conservation listings**

Europe: SPEC category 3 (declining)

UK: amber (European status)

**Long-term trend**

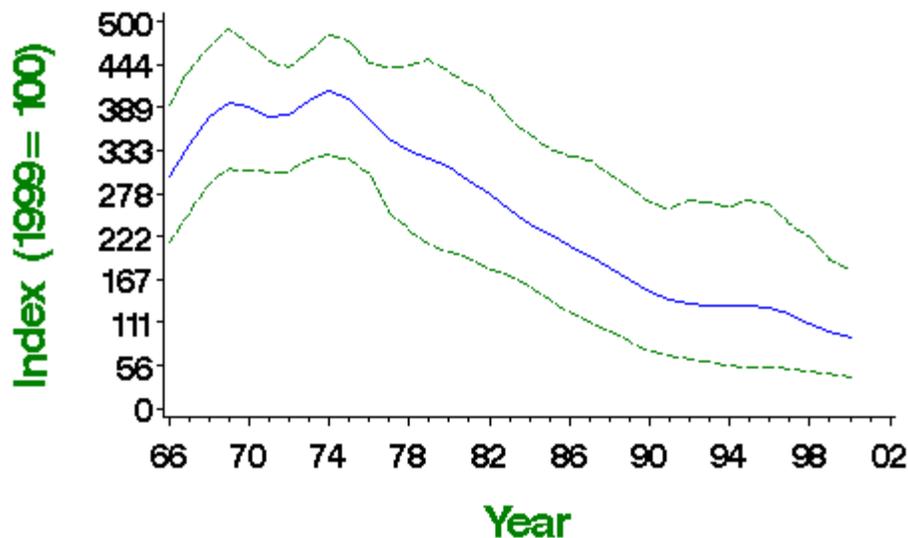

UK: probable decline

**UK population size**

5,400–13,700 pairs in 2000 (1988–91 Atlas estimate updated using CBC trend: [BiE04](#), [APEP06](#)); 78,346 (61,717–96,493) males in 2003 ([Hoodless et al. 2009](#))

**Status summary**

The Woodcock declined rapidly and significantly on CBC plots for the three decades up to 2000. Because CBC did not include many coniferous forests and its plots were concentrated in lowland Britain, however, it is not certain how well this trend represents the whole UK population. Range contractions, that might have had the same cause as the decline in abundance, were recorded concurrently with part of the CBC decline ([Gibbons et al. 1993](#)). Recreational disturbance, the drying out of natural woodlands, overgrazing by deer, declining woodland management, and the maturation of new plantations are possible causes of the Woodcock's decline, but there is no strong hypothesis as yet ([Fuller et al. 2005](#)). BBS is inefficient at recording this scarce, mainly crepuscular species, and cannot continue the index series. The first special survey aimed at monitoring the UK's breeding Woodcock took place in 2003 and has provided a new, much higher baseline population estimate for future monitoring ([Hoodless et al. 2009](#); also, [here](#)). It is important to note, though, that the upward revision of the population estimate is due to new methodology and carries no information about population trends. The CBC decline was discounted in 2009 as a reason for the species' amber listing ([BoCC3](#)), which now rests on the breeding declines recorded across Europe, especially European Russia ([BiE04](#)). Annual **numbers shot** in the UK, which include winter visitors from declining populations in Europe, have increased around threefold since 1945 and are currently running at a historically high level.

England: probable decline

### UK population size

107,000 (99,500–125,000) pairs in 1985–99 ([O'Brien 2005](#): [BiE04](#), [APEP06](#))

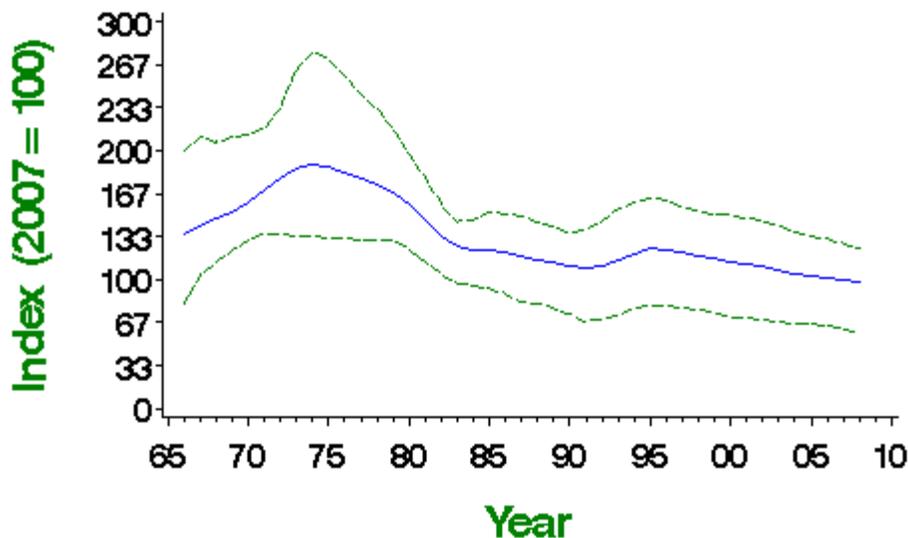

### Status summary

Curlews monitored by CBC were mostly in lowland habitats and may have been affected primarily by drainage of farmland ([Gibbons \*et al.\* 1993](#)). Surveys of breeding birds in wet meadows in England and Wales revealed a decrease of 39% between 1982 and 2002 ([Wilson \*et al.\* 2005](#)). A 2006 survey highlighted the rapid decline of the species across all habitats in Wales, with low breeding success as a plausible mechanism ([Johnstone \*et al.\* 2007](#)). In Northern Ireland, a breeding decline of around 60% occurred between the mid 1980s and 1999 ([Henderson \*et al.\* 2002](#)). BBS data also show that decline has been widespread. WBS data, in contrast, indicate a moderate increase during the 1980s in Curlews nesting alongside waterways. Wintering Curlew abundance showed a shallow long-term increase to around 2000, but has since declined ([Holt \*et al.\* 2009](#)).

## COMMON SANDPIPER

*Actitis hypoleucos*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: SPEC category 3 (declining)

UK: amber (25–50% population decline)

### Long-term trend

UK waterways: moderate decline

### UK population size

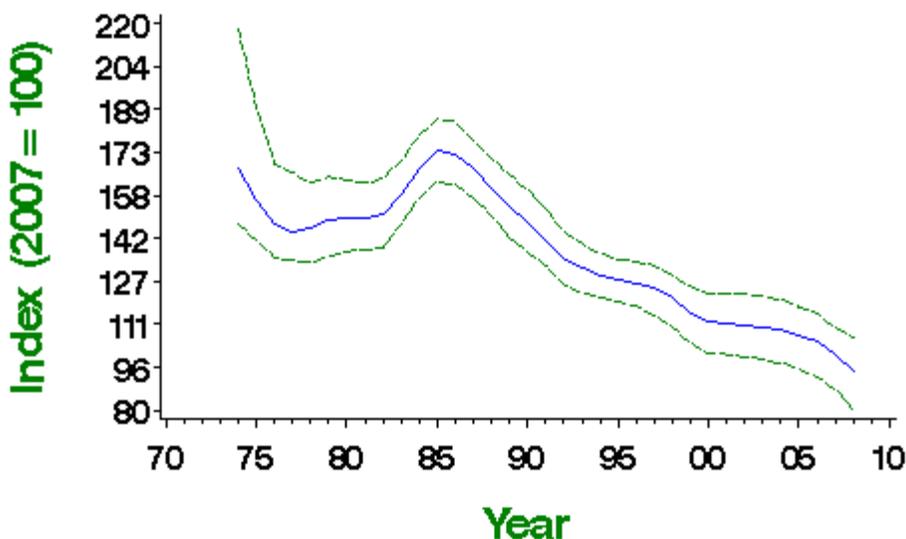

12,000 pairs in 2000 (1988–91 Atlas estimate updated using WBS trend: [BiE04](#), [APEP06](#)); about 24,000 pairs in Britain ([Dougall et al. 2004](#))

### Status summary

WBS/WBBS results for this species show a decline from 1985 onwards (after a more gradual increase) that has yet to be explained. The recent decrease is matched by BBS data from Scotland and from the UK as a whole, and warrants a BTO alert. Poorer breeding success and reduced survival of first-year birds over the winter in West Africa were both suggested as possible reasons for the failure of the Peak District population to recover after a hard-weather event in 1989 ([Holland & Yalden 2002](#)). Following declines during the 1990s in the large Swedish and Finnish populations, and more widely in Europe, the European status of this species is no longer considered 'secure' ([BirdLife International 2004](#)). The mean change across all European countries during the 1990s was a significant decline ([Sanderson et al. 2006](#)). UK clutch sizes appear to have shown a slight decline since the 1960s. The species has recently been moved to the amber list on the strength of its declines in UK and across Europe.

## REDSHANK

### *Tringa totanus*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: SPEC category 2 (declining)

UK: amber (>50% population decline but data possibly unrepresentative, >20% of East Atlantic Flyway population in winter)

### Long-term trend

UK: moderate or rapid decline

### UK population size

38,800 (31,400–44,400) pairs in 1985–99 (O'Brien 2005: BiE04, APEP06)

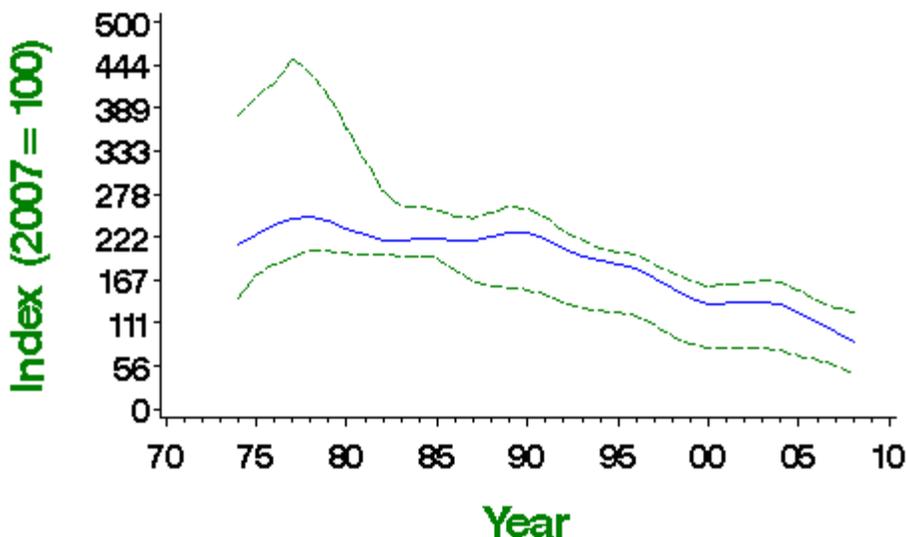

### Status summary

UK population decline has recently been added to the criteria by which Redshank qualifies for amber listing; the scale of decline reported here now meets the red-list criterion, however. Considerable range contraction had occurred from many areas of the UK by 1988–91, probably as a result of the drainage of farmland (Gibbons *et al.* 1993). WBS/WBBS results show a decline along waterways that apparently accelerated during the 1990s. BBS shows continuing overall decrease. Surveys in England and Wales revealed a decrease of 29% in breeding birds in wet meadows between 1982 and 2002 (Wilson *et al.* 2005). The substantial section of the British population that nests on saltmarshes decreased by 23% between 1985 and 1996, apparently as a result of increased grazing pressure (Brindley *et al.* 1998, Norris *et al.* 1998). Wintering populations (augmented by many Icelandic and some other northern European breeders) had been stable since the mid 1980s but have declined in recent seasons (Holt *et al.* 2009). The failure rate of nests at the egg stage has fallen steeply since the 1960s. Numbers have fallen widely across Europe since 1980 (PECBMS 2009).

## FERAL PIGEON

### *Columba livia*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: green (Rock Dove *C. l. livia*)

### Long-term trend

UK: possible increase

### UK population size

>100,000 pairs in 1968–72 (1968–72 Atlas: [APEP06](#));

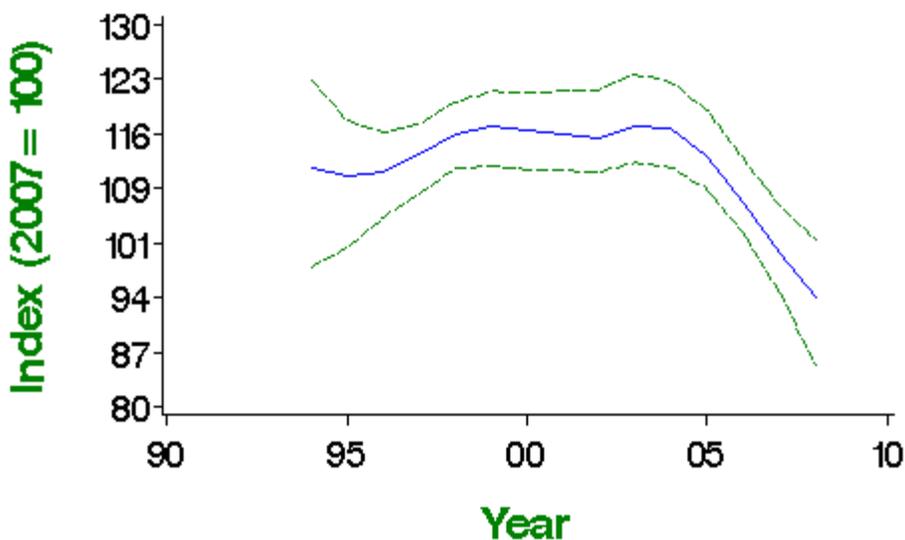

100,000–250,000 pairs in 1988–91 ([BiE04](#))

### Status summary

CBC samples for Feral Pigeon were consistently too small for annual monitoring, and there was no trend information before BBS began in 1994. Breeding atlas data show a 39% increase in occupied 10-km squares between 1968–72 and 1988–91 ([Gibbons \*et al.\* 1993](#)), suggesting that Feral Pigeons may be on an upward trajectory, like the other *Columba* species in the UK. At the time of the first atlas, however, Feral Pigeons were commonly overlooked during bird surveys, and some of the reported subsequent range increase may have been due to greater observer awareness. It is now clear that Feral Pigeons are almost ubiquitous in the UK, nesting in rural as well as urban habitats, and avoiding only the highest ground. No distinction can realistically be drawn between feral birds of domestic origin and true wild-type Rock Doves, although birds of wild-type plumage still predominate on the more remote Scottish islands. In field conditions, it is not usually possible to distinguish between pure native Rock Doves, wild-nesting Feral Pigeons, semicaptive dovecote breeders, and passing racing pigeons, nor between adults and young of the year, and BBS counts are likely to include birds from all of these groups. BBS indices suggest that a minor decrease has occurred in recent years.

## STOCK DOVE

*Columba oenas*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (concentrated in Europe, conservation status favourable)

UK: amber (>20% of European breeding population)

### Long-term trend

England: rapid increase

### UK population size

309,000 territories in 2000 (1988–91 Atlas estimate updated using CBC trend: [BiE04](#), [APEP06](#))

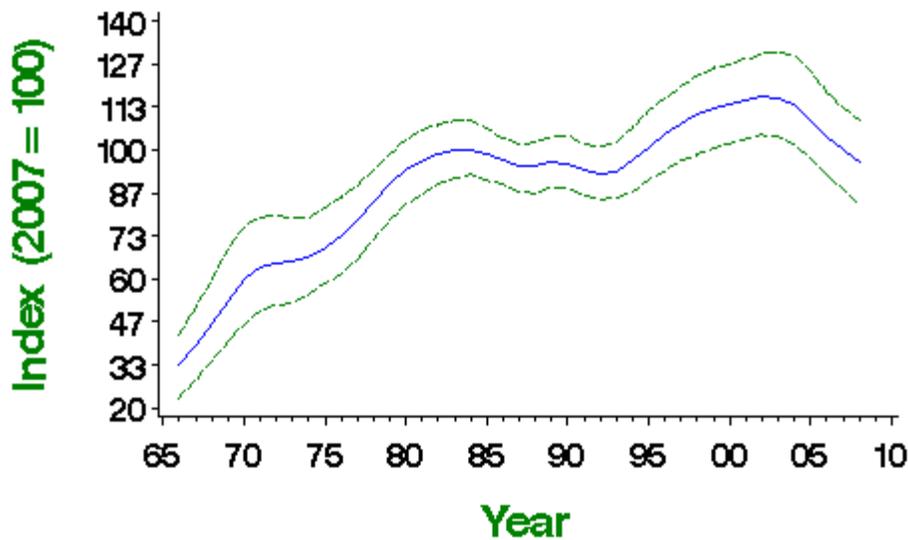

### Status summary

Following release from the lethal and sublethal effects of the organochlorine seed-dressings used in the 1950s and early 1960s, Stock Dove populations have increased very substantially ([O'Connor & Mead 1984](#)). Numbers appeared to level off in the early 1980s, and entered a further increasing phase in the early 1990s. Recent indices suggest that numbers have fallen significantly in the last few years. The increase in nest failure rates at the egg stage, now reversed, was not detectable in farmland habitats alone ([Siriwardena et al. 2000b](#)). Overall, nest failure rates have fallen substantially since the 1980s and there has been a major increase in the number of fledglings raised per breeding attempt.

## WOODPIGEON

*Columba palumbus*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (concentrated in Europe, conservation status favourable)

UK: green

### Long-term trend

UK, England: rapid increase

### UK population size

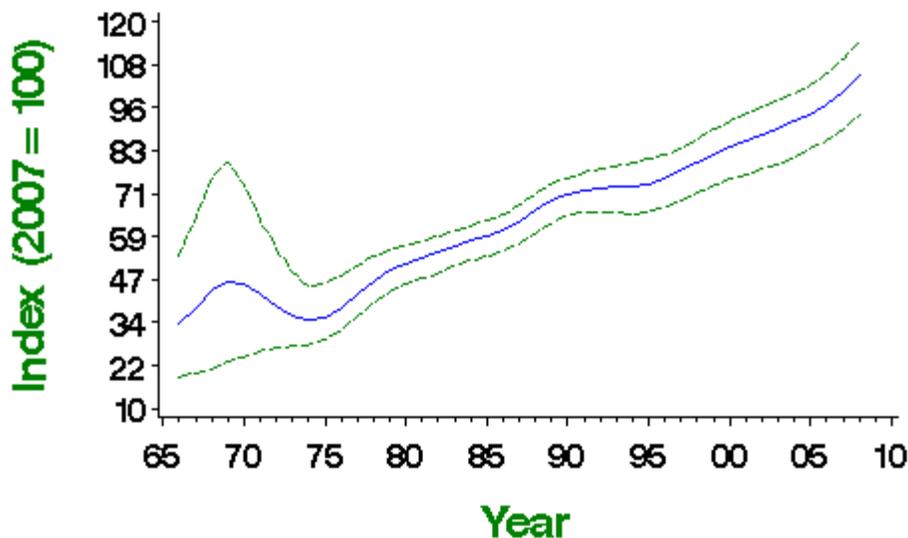

2,570,000–3,160,000 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

### Status summary

The CBC/BBS trend for this species is of a steady, steep increase since at least the mid 1970s. The spread of intensive arable cultivation, especially of oilseed rape, which has been shown to promote overwinter survival, may explain the rise in numbers ([Gibbons \*et al.\* 1993](#)). Since 1994, BBS has recorded significant increase in the UK, and in England, Wales and Northern Ireland separately, but stability in Scotland. [O'Connor & Shrubbs \(1986\)](#) found that the breeding season had advanced in response to the switch to autumn sowing, and thus earlier ripening, of cereals, with more pairs nesting in May and June and relatively fewer in July–September. A trend toward earlier nesting could have led CBC, with its fieldwork finishing in early July, to overestimate the rate of increase ([Marchant \*et al.\* 1990](#)). Numbers have risen widely in Europe since 1980 ([PECBMS 2009](#)).

## COLLARED DOVE

### *Streptopelia decaocto*

- Population changes
- Productivity trends
- Additional information

### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)  
 UK: green

### Long-term trend

UK, England: rapid increase

### UK population size

298,000 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

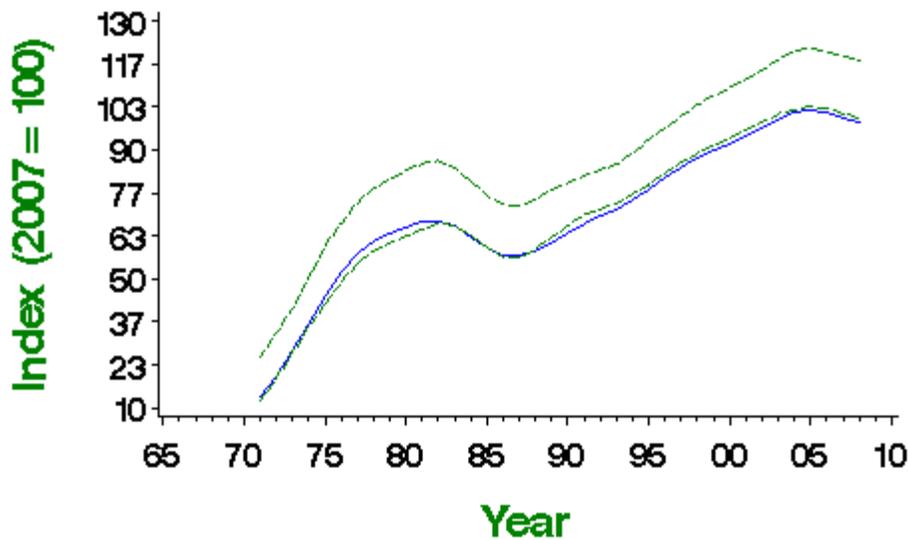

### Status summary

Collared Dove abundance has increased rapidly since the species first colonised Britain in 1955. From just four birds known to be present in that year, the population was put conservatively at 15,000–25,000 pairs by 1970 ([Hudson 1972](#)). The CBC index showed an almost exponential rise as colonisation continued during the early 1970s, but had levelled off by about 1980. BBS shows continuing increases, at least in England and Wales. The UK population size now rivals that of [Stock Dove](#). Despite the population increase, the number of fledglings per breeding attempt has also increased, perhaps as the species has become better adapted to its new environment. The species has increased widely across Europe since 1980 ([PECBMS 2009](#)).

## TURTLE DOVE

*Streptopelia turtur*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: SPEC category 3 (declining)

UK: red (>50% population decline)

UK Biodiversity Action Plan: [click here](#)

### Long-term trend

UK, England: rapid decline

### UK population size

44,000 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

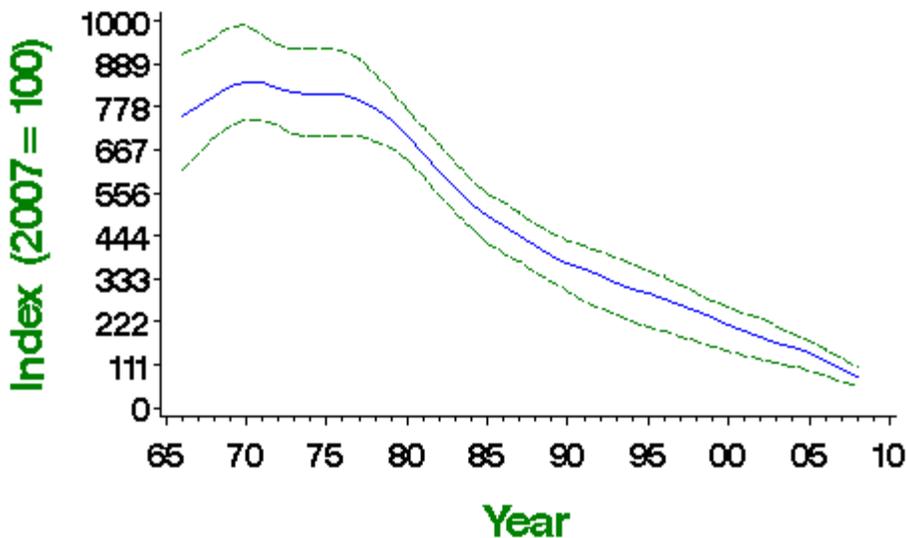

### Status summary

The CBC/BBS trend is of severe declines in Turtle Dove abundance, beginning in the late 1970s and continuing to the present. Hunting during migration is a possible cause of the UK decline, to add to those related to agricultural intensification that have been postulated for other farmland seed-eaters ([O'Connor & Shrubbs 1986](#), [Krebs \*et al.\* 1999](#)). Analysis of nest record cards and ringing data for farmland Turtle Doves suggests, although without statistical significance, that productivity per nesting attempt has increased while annual survival has fallen ([Siriwardena \*et al.\* 2000a, 2000b](#), [Browne \*et al.\* 2005](#)). [Browne & Aebischer \(2004, 2005\)](#) conclude that Turtle Doves today have a substantially earlier close to the breeding season and consequently produce barely half the number of clutches and young per pair they did in the 1960s. Thus, the recovery of Turtle Doves in Britain would benefit from the provision and sympathetic management of nesting as well as foraging habitats. Turtle Dove is one of the most strongly declining bird species in Europe, having decreased at an annual rate of 4% during 1980–2006 ([PECBMS 2009](#)). Conditions in winter may also be influencing trends: a recent study has demonstrated a positive correlation between survival rate among breeding adults in France and food supply in West Africa, as measured by cereal production ([Eraud \*et al.\* 2009](#)).

## RING-NECKED PARAKEET

*Psittacula krameri*

- Population changes
- Productivity trends
- Additional information

### Conservation listings

Europe: not evaluated (introduced)

UK: not listed (introduced)

### Long-term trend

England: rapid increase

### UK population size

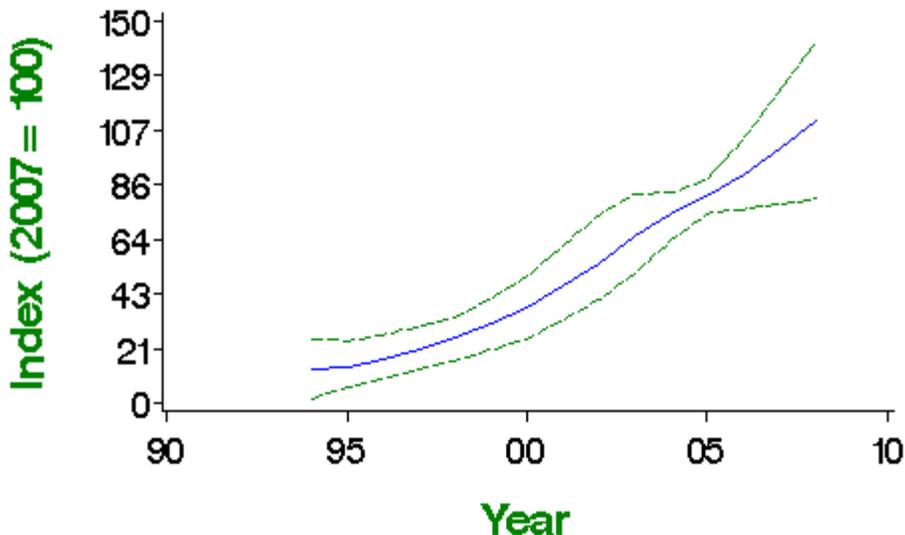

4,300 individual adults in winter 2000/01 ([Butler 2002: APEP06](#)); further growth ([Holling & RBBP 2007b](#))

### Status summary

Following escapes and releases over many decades, this African and Asian parrot began breeding annually in the UK in 1969. Substantial but highly localised self-sustaining populations of this species have since built up, with the two largest being in the southern part of Greater London and in the Isle of Thanet, east Kent. Population modelling has revealed that populations in Greater London have increased by approximately 30% per year, and those in Thanet by 15% per year, but that the range has expanded by only 0.4 km per year in the Greater London area and so far not at all in Thanet ([Butler 2003](#)). A single roost site used each night by birds from throughout the south London range held 6,818 birds in August 2003 ([Holling & RBBP 2007b](#)). There have been subsequent estimates of up to 30,000 birds, but no source can yet be identified for such figures. The species has already been reported causing economic damage to crops, as has occurred elsewhere in its native and introduced range ([Butler 2003](#)). A recent study in Belgium has identified negative effects on breeding [Nuthatch](#), but not on other native hole-nesting species, such as [Starling](#) ([Strubbe & Matthysen 2007](#)).

## CUCKOO

*Cuculus canorus*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: red

UK Biodiversity Action Plan: priority species

### Long-term trend

England: rapid decline

### UK population size

9,600–20,000 pairs in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

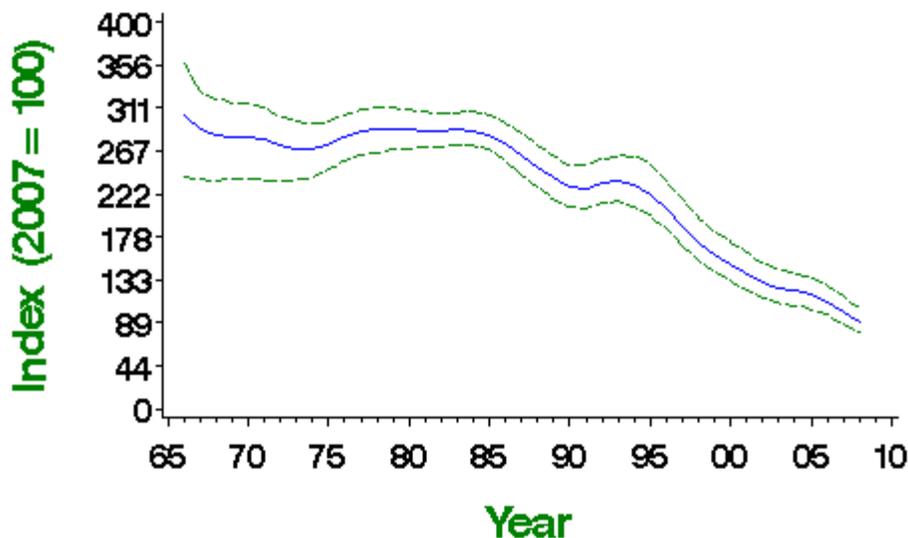

### Status summary

The CBC/BBS trend shows Cuckoo abundance to have been in decline since the early 1980s. The species was moved in 2002 from the green to the amber list, and in the latest review met red-list criteria. The sensitivity of CBC to change in this species may have been relatively low, mainly because Cuckoo territories were typically larger than census plots ([Marchant et al. 1990](#)). BBS shows a continuing strong decline in England and Wales, but apparent increase in Scotland. Cuckoo numbers may have fallen because the populations of some key host species, such as [Dunnock](#) and [Meadow Pipit](#), have declined ([Brooke & Davies 1987](#)). Decreases among certain British moths may have reduced food supplies for returning adults, and the species may also be suffering difficulties on migration or in winter ([Glue 2006](#)). Strong variation in Cuckoo population trends between habitats may reflect regional differences in the main hosts and differing trends in Cuckoo breeding success among those host species: Cuckoos increased significantly during 1994–2006 in lowland semi-natural grass, heath and bog but decreased in almost all other habitat types ([Newson et al. 2009](#)).

## BARN OWL

*Tyto alba*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: SPEC category 3 (declining)

UK: amber (25–50% distribution decline)

### Long-term trend

UK: decline

### UK population size

4,000 (3,000–5,000) pairs in 1995–97 ([Toms et al. 2001](#): [BiE04](#), [APEP06](#))

### Status summary

Distributional data provide good evidence for a decline in this species that lasted throughout the 20th century, although annual monitoring started only very recently. Productivity has tended to improve since the 1950s and 1960s when Barn Owls appear to have been affected by organochlorine pesticides ([Percival 1990](#)). A national census during 1995–97, organised jointly by Hawk & Owl Trust and BTO, provided a replicable baseline population estimate ([Toms et al. 2000, 2001](#); for more information, click [here](#)). The lack of annual population change data for this species is now being addressed by the BTO's [Barn Owl Monitoring Programme \(BOMP\)](#), which began in 2000; additional nest record, ringing and biometric information is also being collected through this scheme ([Leech et al. 2005](#)). BOMP already provides evidence that fewer pairs attempt to nest following cold or wet winters ([Leech et al. 2006a](#)). In earlier decades, the plight of such a charismatic and popular bird led to extensive releasing of captive-bred birds in well-meaning attempts at restocking: by 1992, when licensing became a requirement for such schemes, it was estimated that between 2,000 and 3,000 birds were being released annually by about 600 operators, although many birds died quickly and few would have joined the nesting population ([Balmer et al. 2000](#)). More recently, the erection of Barn Owl nest boxes, already numbering c. 25,000 by the mid 1990s, has enabled the species to occupy areas (notably the Fens) that were previously devoid of nesting sites, and may have been a factor in improving nesting success. RBBP provide a county breakdown of 2005 nesting totals [here](#) ([Holling & RBBP 2008](#)).

## LITTLE OWL

*Athene noctua*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: SPEC category 3, declining

UK: not listed (introduced)

### Long-term trend

UK, England: probable decline

### UK population size

5,800–11,600 pairs in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

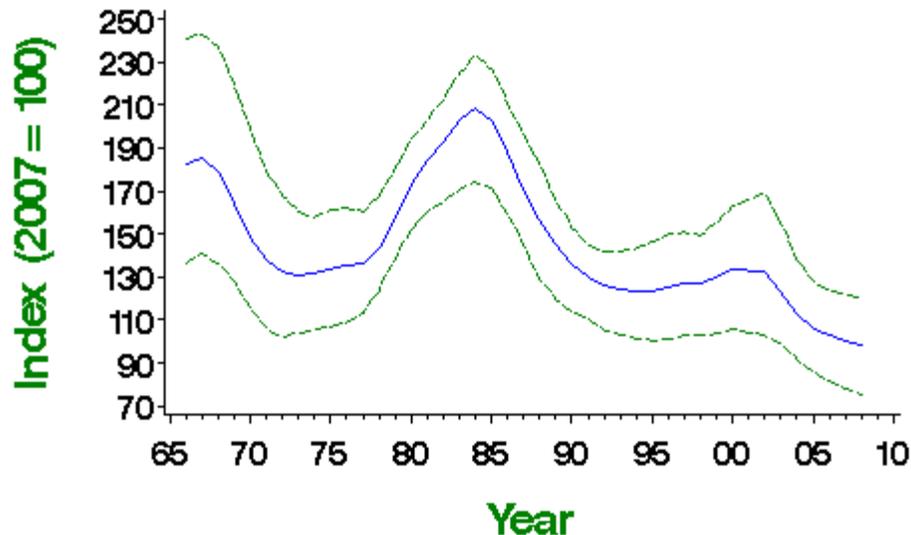

### Status summary

The CBC/BBS trend for Little Owl in the UK shows very wide variation, but a downturn in recent seasons suggests that a moderate long-term decline probably lies behind the observed fluctuations. Trends are poorly known, however, because the species has large breeding territories and, being largely inactive during the day, is difficult to detect except by dedicated surveys. A population estimate of c. 7,000 pairs from the BTO/Hawk & Owl Trust's [Project Barn Owl \(Toms et al. 2000\)](#) is the first replicable estimate for Little Owls in the UK. No trends are evident in the number of fledglings per breeding attempt, but few nest records are available.

## TAWNY OWL

*Strix aluco*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (concentrated in Europe, conservation status favourable)

UK: green

### Long-term trend

UK, England: probably stable

### UK population size

19,400 pairs in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

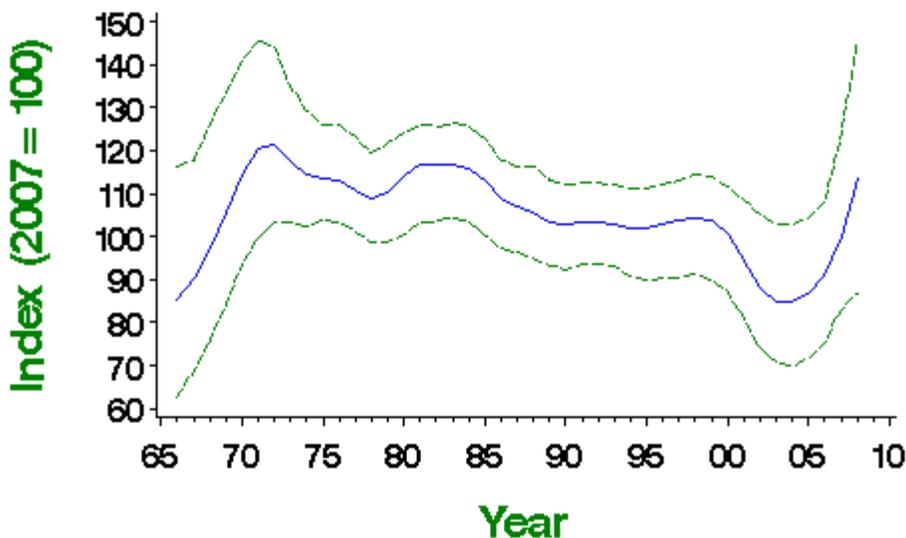

### Status summary

As a nocturnal species, Tawny Owl is covered relatively poorly by the BTO's monitoring schemes. The pattern shown by CBC/BBS is a relatively stable one, however, in keeping with the longevity, sedentary behaviour, and slow breeding rate of this species. There has been a shallow downward trend in the index since the early 1970s. It may be relevant to this possible long-term decline that [Gibbons \*et al.\* \(1993\)](#) found evidence for a contraction of the species' UK range between the two atlas periods. The substantial improvements in nest success during the c.29-day egg stage could be linked to the declining impact of organochlorine pesticides, which were banned in the early 1960s. The numbers of fledglings per breeding attempt have increased steeply. Special post-breeding surveys of this species were conducted in autumn 2005 ([click here](#)), following methodology established by an earlier survey in 1989 ([Percival 1990](#)).

## NIGHTJAR

### *Caprimulgus europaeus*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: SPEC category 2, (declining)

UK: red (>50% distribution decline)

UK Biodiversity Action Plan: [click here](#)

### Long-term trend

UK: uncertain

### UK population size

3,400 males in 1992 ([Morris et al. 1994: BiE04, APEP06](#)); 4,600 males in 2004 ([Conway et al. 2007](#))

### Status summary

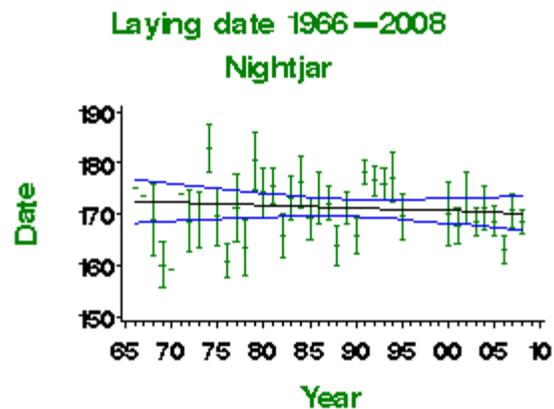

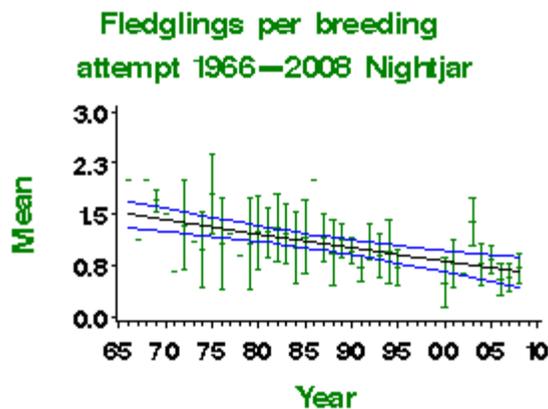

Following a catastrophic decline in range of more than 50% of 10-km squares between breeding atlases, the 1992 national survey revealed a welcome increase of 50% in population size since 1981, probably due to the increased availability of young forest habitat as plantations were felled and replanted ([Morris et al. 1994](#)). A [National Nightjar Survey](#) in 2004 revealed that a further 36% increase had taken place in the UK population in 12 years, with a 2.6% increase in the number of 10-km squares occupied ([Conway et al. 2007](#)). There was evidence of population declines and range contractions since 1992, however, in North Wales, northwest England, and Scotland. Although annual nest record sample are very small, the increases in nest failure rates and decreases in clutch and brood sizes have resulted in the inclusion of Nightjar on the NRS concern list ([Leech & Barimore 2008](#)). A steep linear decrease is evident in the number of fledglings per breeding attempt. A recent study suggests that nest failure is most likely in areas heavily frequented by walkers and dogs ([Langston et al. 2007](#)).

## COMMON SWIFT

*Apus apus*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: amber (25–50% decline)

### Long-term trend

UK: decline

### UK population size

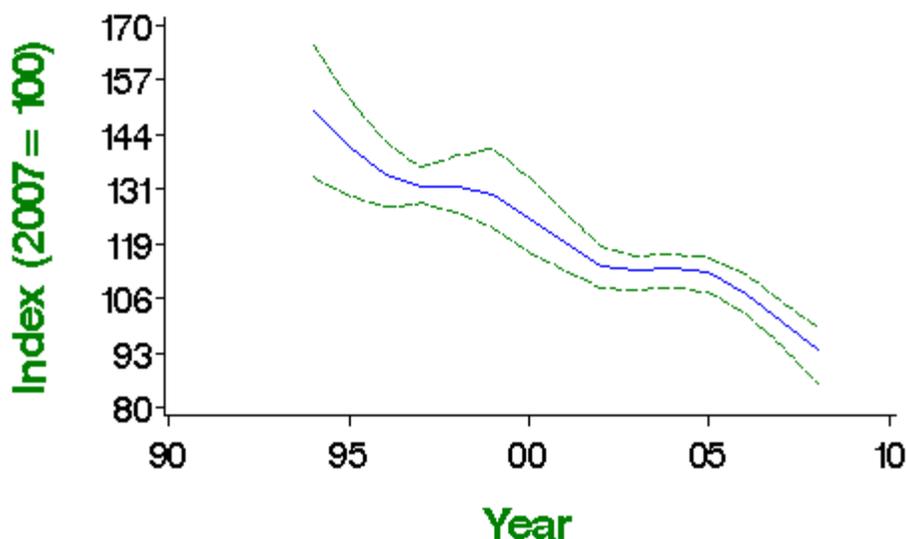

85,000 pairs in 1990 (1988–91 Atlas: [APEP06](#)); 20,000–100,000 pairs in 2000 ([BiE04](#))

### Status summary

Swifts were not monitored before the inception of the BBS. Their monitoring is complicated by the difficulty of finding occupied nests, by the weather-dependent and sometimes extraordinary distances from the nest at which breeding adults may forage, and by the often substantial midsummer influx of non-breeding individuals to the vicinity of breeding colonies. Since Swifts do not normally begin breeding until they are four years old, non-breeding numbers can be large. BBS results suggest steep declines in England, Scotland and Wales. Many Swifts seen on BBS visits will not be nesting nearby, however, and the relationship between BBS transect counts and nesting numbers is not properly understood so far. On the strength of the BBS decline, Swift has recently been moved from the green to the amber list of conservation concern ([Eaton et al. 2009](#)). [Concern for Swifts](#), a small private organisation, is trying to promote the deliberate provision of nesting sites for this species, as so many suitable cavities are being lost to redevelopment. It is also gathering information on populations to try to clarify the breeding status of the species.

## KINGFISHER

*Alcedo atthis*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: SPEC category 3, depleted

UK: amber (European status)

### Long-term trend

UK waterways: fluctuating, with no long-term trend

### UK population size

4,800–8,000 pairs in 2000 (1988–91 Atlas estimate updated using WBS trend: [BiE04](#), [APEP06](#))

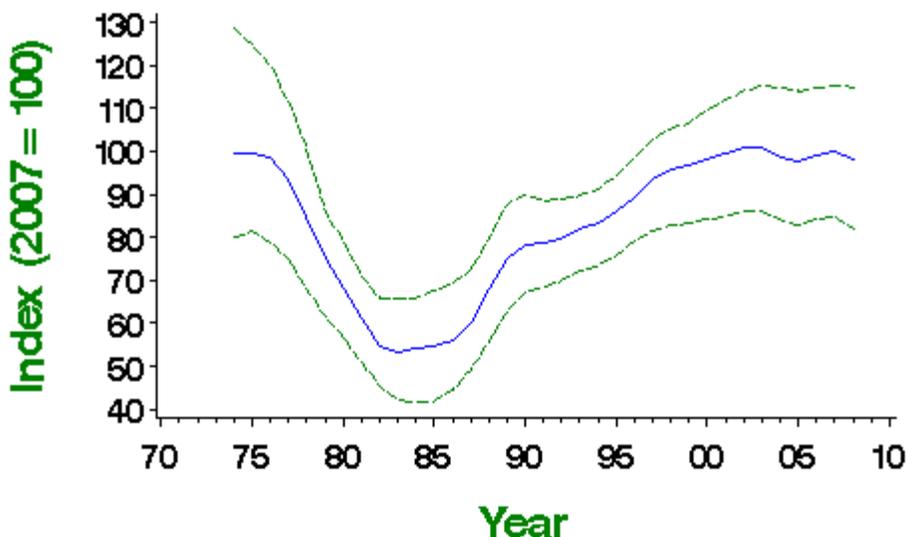

### Status summary

The Kingfisher declined along linear waterways (its principal habitat) until the mid 1980s, since when it seems to have made a complete recovery. The decline was associated with a contraction of range in England ([Gibbons \*et al.\* 1993](#)). Kingfishers suffer severe mortality during harsh winters but, with up to three broods in a season, and up to six chicks in a brood, their potential for rapid population growth is unusually high. Amber listing of this species in the UK results from its 'depleted' status in Europe as a whole, following declines between 1970 and 1990 ([BirdLife International 2004](#)).

## GREEN WOODPECKER

*Picus viridis*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: SPEC category 2 (depleted)

UK: amber (European status)

### Long-term trend

England: rapid increase

### UK population size

24,200 pairs in 2000 (1988–91 Atlas estimate updated using

CBC trend: [BiE04](#), [APEP06](#))

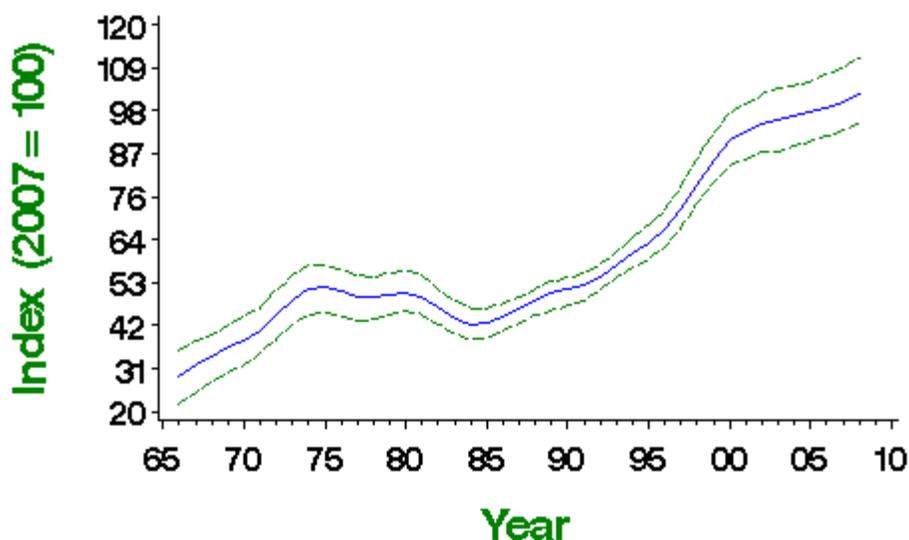

### Status summary

Green Woodpecker populations have risen steadily in Britain since 1966, except for a period of stability or shallow decline centred around 1980 that was probably the result of a series of harsh winters. There was considerable range expansion in central and eastern Scotland between the 1968–72 and 1988–91 atlas periods. Recent results indicate that the current phase of increase is continuing across England, but not Wales, where some contraction of range has recently been detected. The ecological factors underlying the increase are not yet known but, given the species' susceptibility to cold weather, it may be related to climate change. Numbers have risen widely in Europe since 1980 ([PECBMS 2009](#)).

### *Lullula arborea*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: SPEC category 2 (depleted)

UK: amber (European status, long-term UK range contraction, localised UK breeding)

UK Biodiversity Action Plan: [click here](#)

### Long-term trend

UK: increase

### UK population size

1,426–1,552 pairs in 1997 ([Wotton & Gillings 2000](#):

[APEP06](#), rounded to 1,400–1,600 [BiE04](#)); 3,064 (2,472–

3,687) territories in 2006 ([Conway et al. 2009](#))

### Status summary

This species is too rare and restricted in range for population changes to be monitored annually by BTO volunteer surveys. A 62% reduction occurred in the number of 10-km squares occupied between 1968–72 and 1988–91; the species had ceased to breed in Wales and in several southern English counties over this period ([Gibbons et al. 1993](#)). [Sitters et al. \(1996\)](#) report that the UK population increased from c.250 pairs in 1986 to c.600 pairs in 1993, probably helped by mild winters and increased habitat availability due to storm damage in plantations, forest restocking, and heathland management. A repeat national survey in 1997 showed that the population had increased further, accompanied by expansion of the range into new areas ([Wotton & Gillings 2000](#); for more information, click [here](#)). A further repeat in 2006 recorded an increase since 1997 of 88% accompanied by major range expansion, with a pair breeding in Wales for the first time since 1981 ([Conway et al. 2009](#); also [here](#)). Farmland setaside, especially close to forest, was valuable additional habitat for the expanding population, although clutch sizes may be lower there than in more traditional habitats ([Wright et al. 2007](#)). Climate change may benefit Woodlark, because it is able to make more nesting attempts in warmer years ([Wright et al. 2009](#)). The small NRS sample suggests that nest failure rates have become less frequent at the egg stage. There has been no trend, however, in the number of fledglings per breeding attempt. Human disturbance at heathland sites apparently reduces population density, but the effects are partly offset by higher breeding productivity at lower densities ([Mallord et al. 2007](#)). The species' partial recovery in numbers and range resulted in a move from the red to the amber list at the 2009 review ([Eaton et al. 2009](#)).

**SKYLARK***Alauda arvensis*

- Population changes

- Productivity trends

- Additional information

**Conservation listings**

Europe: SPEC category 3 (depleted)

UK: red (species level, race *arvensis*); amber (race *scotica*, >20% of European breeders)UK Biodiversity Action Plan: [click here](#)**Long-term trend**

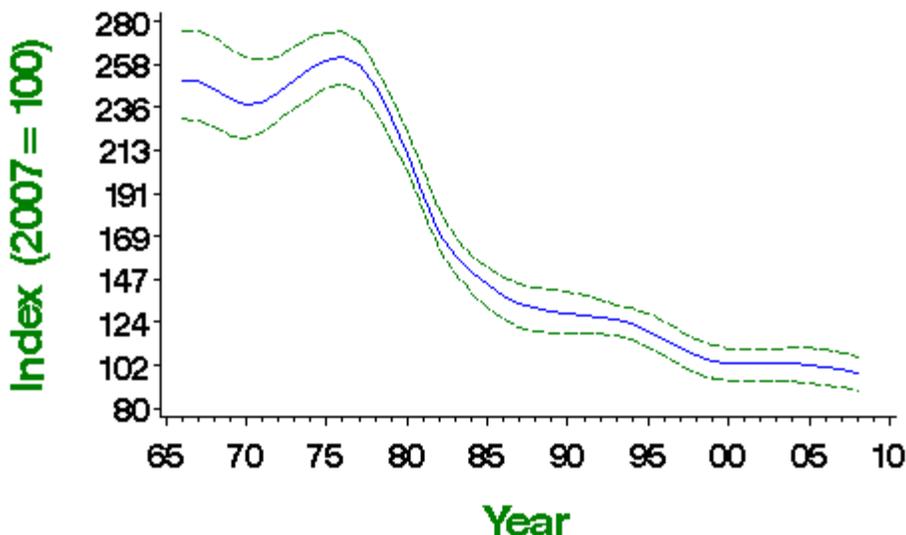

England: rapid decline

**UK population size**

1,785,000 territories in 2000 (1988–91 Atlas estimate

updated using CBC/BBS trend: [BiE04](#), [APEP06](#));801,000–1,003,000 pairs in Britain in 1997 ([Browne et al. 2000](#))**Status summary**

The Skylark declined rapidly from the mid 1970s until the mid 1980s, when the rate of decline slowed; more recent data show further decline, however, at least in England. Considerable effort by BTO and other researchers in recent years has indicated that the most likely cause of the decline is the change to autumn sowing of cereals: this practice restricts opportunities for late-season nesting attempts, because the crop is by then too tall, and may depress overwinter survival by reducing the area of stubbles ([Wilson et al. 1997](#), [Donald & Vickery 2000, 2001](#); for more information, click [here](#)). [Chamberlain & Siriwardena \(2000\)](#) have provided a general review of the effects of agricultural practice on Skylark population trends. More recently, [Gillings et al. \(2005\)](#) have identified better population performance in areas with extensive winter stubble, presumably because overwinter survival is relatively high. Breeding success per nesting attempt increased during the steepest period of decline ([Chamberlain & Crick 1999](#), [Siriwardena et al. 2000b](#)), but since 2000 has shown signs of reversal. Leaving small, rectangular patches of bare ground ('[Skylark plots](#)') within autumn-sown cereals appears to provide many of the benefits of spring-sown cereals at very low cost to the farmer ([Donald & Morris 2005](#)). Numbers have fallen steeply across in Europe since 1980 ([PECBMS 2009](#)).

## SAND MARTIN

*Riparia riparia*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: SPEC category 3 (depleted)

UK: amber (European status)

### Long-term trend

UK: fluctuating, with no long-term trend

### UK population size

85,000–270,000 nests in 1990 (1988–91 Atlas:

[APEP06](#)); 66,300–211,000 pairs in 2000 (updated using

WBS trend: [BiE04](#))

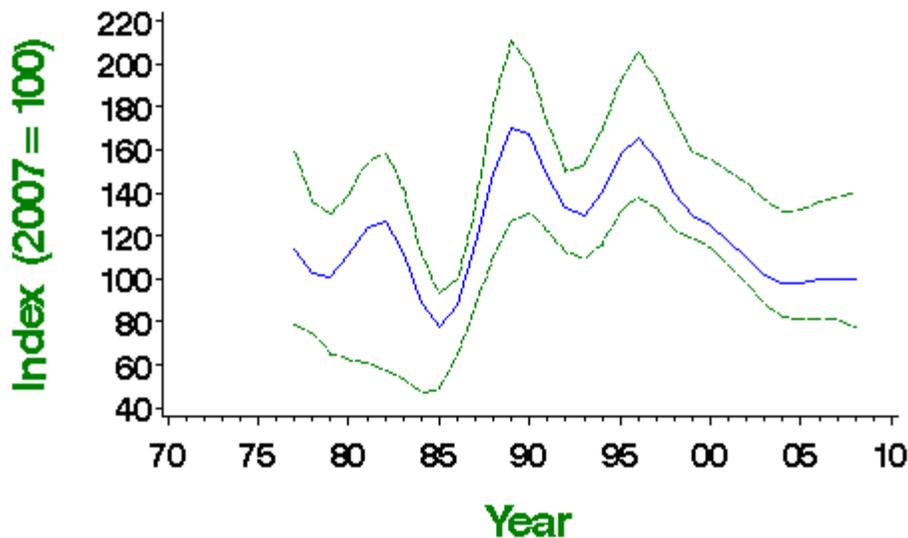

### Status summary

This species is unusually difficult to monitor, because active and inactive nest holes are difficult to distinguish, and because whole colonies frequently disperse or shift to new locations as suitable sand cliffs are created and destroyed. WBS counts, which are of apparently occupied nest holes along riverbanks, suggest a stable or shallowly increasing population, with wide fluctuations, although the ongoing decrease since the late 1990s has been steep enough to raise BTO alerts. BBS counts, which are of birds seen, show clearly that large year-to-year changes occur, but do not yet reveal a clear long-term trend. Nest record samples are small, but indicate that nest failure rates have decreased enormously since the 1960s; clutch size has increased, but brood size has fallen and no trend can be detected in the numbers of fledglings per breeding attempt. Rainfall in the species' trans-Saharan wintering grounds prior to the birds' arrival promotes annual survival and thus abundance in the following breeding season ([Szép 1995](#)). Annual survival rates from RAS sites in the UK for 1990–2004 were correlated positively with minimum monthly rainfall during the wet season in West Africa ([Robinson et al. 2008](#)). More recently, it has been discovered that summer rainfall on the breeding grounds has a negative influence on survival rates through the following winter ([Cowley & Siriwardena 2005](#)).

**SWALLOW***Hirundo rustica*

• Population changes

• Productivity trends

• Additional information

**Conservation listings**

Europe: SPEC category 3 (depleted)

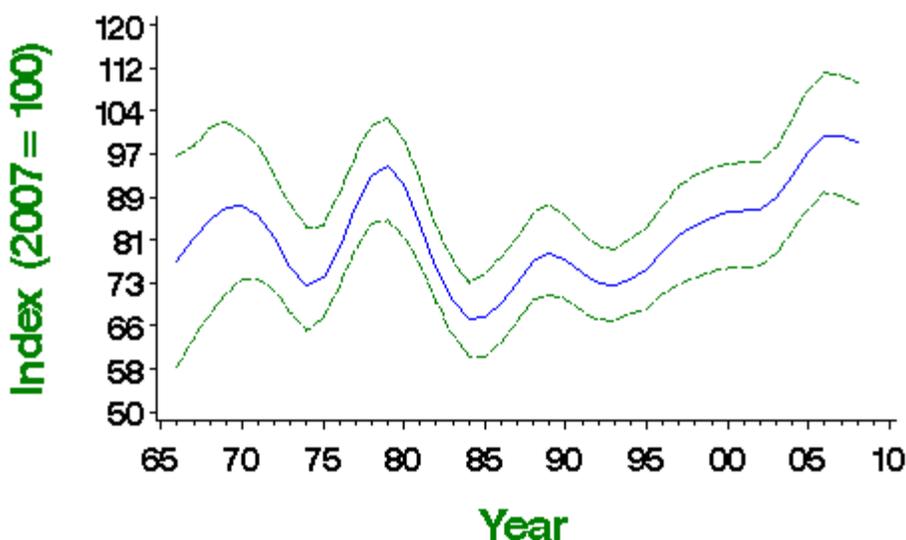

UK: amber (European status)

**Long-term trend**

England: possible shallow increase

**UK population size**726,000 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))**Status summary**

Swallow was originally amber-listed partly on the strength of a perceived CBC decline, but continues to qualify through its widespread decline across the European continent ([BirdLife International 2004](#)). Modern methods of estimating population change from CBC give evidence of fluctuations but not for long-term decline in the UK ([Robinson et al. 2003](#)). BBS data suggest increases throughout the UK since 1994. Analysis has shown that the population fluctuations are most strongly related to variable losses on their wintering grounds ([Baillie & Peach 1992](#)). Population change has been shown to be correlated with rainfall in the western Sahel prior to the birds' spring passage through West Africa, but with neither cattle numbers nor nest-site availability in the UK ([Robinson et al. 2003](#)). Annual survival rates from RAS sites in the UK for 1998–2004 were correlated positively with mean monthly rainfall during the early austral summer in southern Africa ([Robinson et al. 2008](#)). It is likely that, in eastern parts of the UK, the loss of livestock farming and grazed grassland, together with arable intensification, has caused the Swallow population to decline, while an increase in the area of pasture in the west and north has promoted a population increase which apparently has more than compensated for declines elsewhere ([Evans & Robinson 2004](#)). A link between regional changes in the availability of preferred feeding habitats and the regional patterns of UK population change again suggests that habitat change on the breeding grounds may explain population trend, at least partly ([Henderson et al. 2007](#)). Clutch and brood sizes increased up to the late 1980s, and may now be falling again, while the numbers of fledglings per breeding attempt show no trend. Climatic warming is leading to both an earlier start and later finish to the breeding season for European Swallows, but there has been increased chick mortality in hot, dry summers and reduced post-fledging survival because of poor conditions for birds migrating through North Africa ([Turner 2009](#)).

## HOUSE MARTIN

*Delichon urbicum*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: SPEC category 3 (declining)

UK: amber (25–50% population decline)

### Long-term trend

UK: probable decline

### UK population size

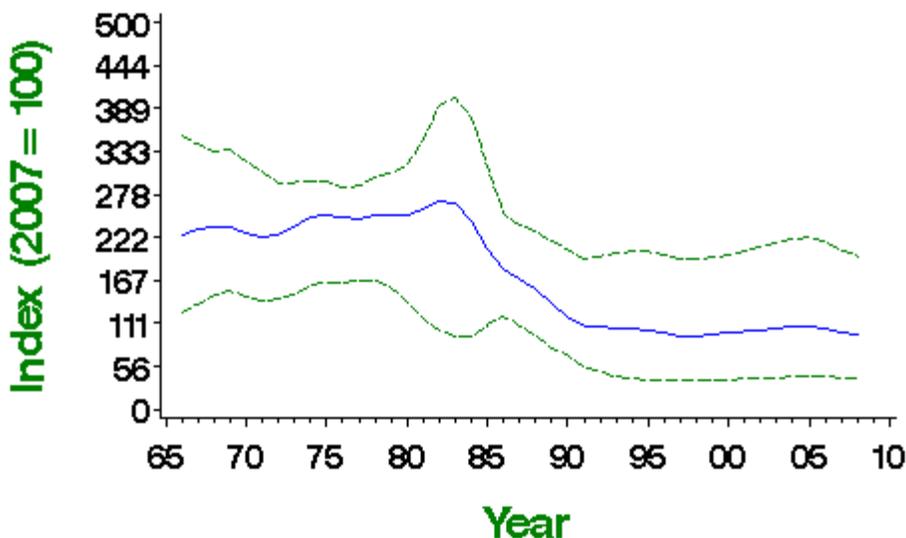

273,000–535,000 pairs in 2000 (1988–91 Atlas estimate updated using CBC trend: [BiE04](#), [APEP06](#))

### Status summary

The House Martin's loosely colonial habits and strong association with human settlements mean that it is extraordinarily difficult to monitor. Anecdotal evidence of decline is often unreliable, because demise of a colony may be balanced by single nests or small groups becoming established elsewhere. For these reasons, study areas should be large, covered thoroughly, and ideally randomly selected. The available long-term data suggest a rapid decline, although BBS shows overall increase since 1994. The species was moved from the green to the amber list in 2002, because of moderate decline in the CBC trend for 1974–99, and is newly listed as of European concern following declines elsewhere in Europe ([BirdLife International 2004](#)). The mean change across all European countries during the 1990s was a significant decline ([Sanderson et al. 2006](#)). Annual survival rates from RAS sites in the UK for 1994–2004 were correlated positively with maximum monthly rainfall in West Africa; some decline in survival rate is apparent over this period but does not correspond to the population decline ([Robinson et al. 2008](#)).

## TREE PIPIT

### *Anthus trivialis*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: red

UK Biodiversity Action Plan: priority species

### Long-term trend

England: rapid decline

### UK population size

74,400 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

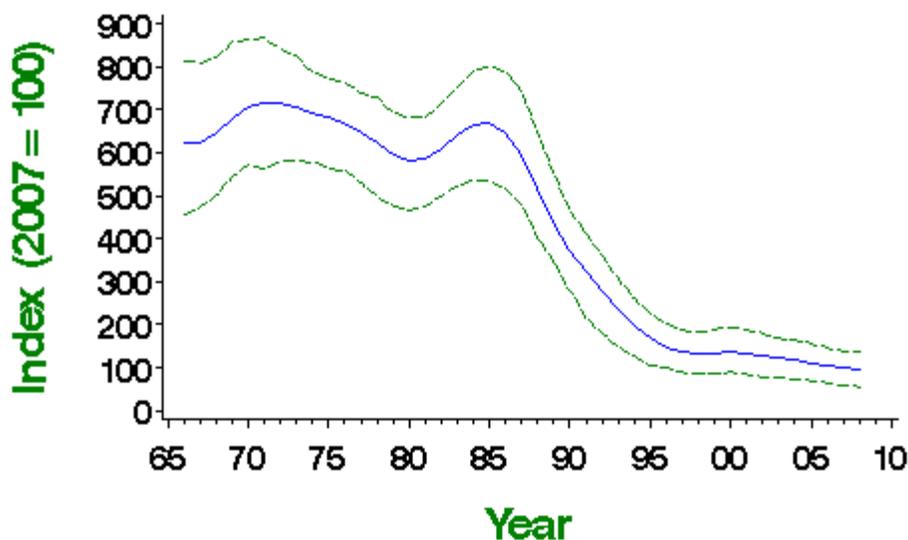

### Status summary

Tree Pipits occur in greatest abundance in Wales, northern England and Scotland, and thus the marked CBC decline between the two atlas periods may reflect the range contraction that occurred then in central and southeast England ([Gibbons \*et al.\* 1993](#)). Since 1994, CBC/BBS data have shown further severe decrease, especially in England. The causes of the population decline are unclear, but may be linked to changing forest structure, as new plantations mature, and reduced management of lowland woods ([Fuller \*et al.\* 2005](#)). In Thetford Forest, Tree Pipits prefer large blocks of habitat and benefit from targeted management such as the retention of mature trees for use as songposts ([Burton 2007](#)). There has been an increase in brood size and a substantial decline in failure rates over the 17-day egg stage; the species is on the NRS concern list, however, because of an overall decrease in nest survival ([Leech & Barimore 2008](#)). Although the species has no European conservation listing as yet, numbers have fallen widely in Europe since 1980 ([PECBMS 2009](#)), and the mean change across all European countries during the 1990s was a significant decline ([Sanderson \*et al.\* 2006](#)). The species was moved from the green to the amber list in 2002, and most recently to red, on the strength of its UK population decline ([Eaton \*et al.\* 2009](#)).

## MEADOW PIPIT

*Anthus pratensis*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (concentrated in Europe, conservation status favourable)

UK: amber (25–50% population decline)

### Long-term trend

England: moderate decline

### UK population size

1,680,000 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

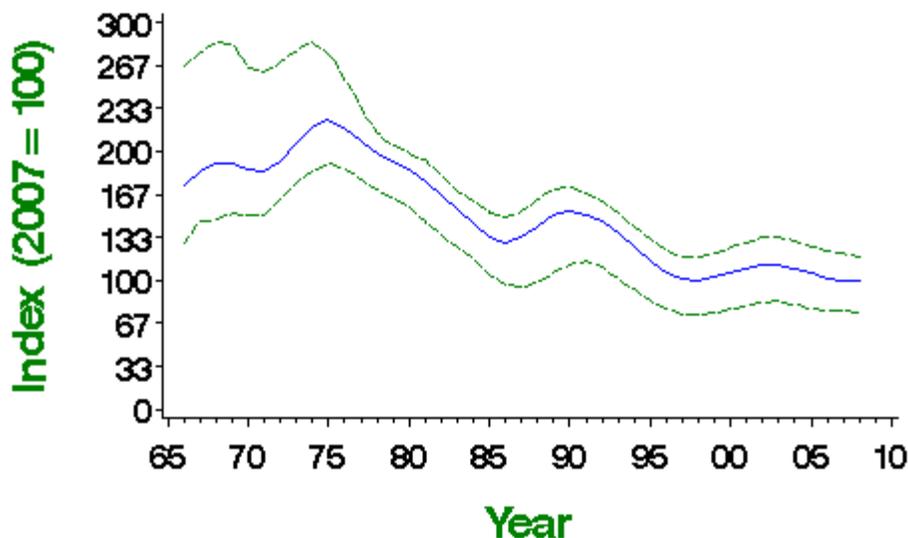

### Status summary

The CBC/BBS trend has been downward since the mid 1970s, accompanied by a range contraction from lowland England ([Gibbons et al. 1993](#)). Meadow Pipits are partial migrants and conditions on the Iberian wintering grounds have been linked to the decline, as have losses of marginal land from parts of the breeding range ([Gibbons et al. 1993](#)). Moorland, the key Meadow Pipit habitat, was not covered well by the CBC, leading to some doubt about the significance of the early results for this species, but BBS now provides more representative monitoring and has enabled the species to move from the green to the amber list. Nest failure rates during the 12-day nestling stage have declined markedly, which may reflect the loss of birds from suboptimal habitat, but no trend is evident in the number of fledglings per breeding attempt. A trend towards earlier laying is probably related to climate change ([Crick & Sparks 1999](#)). A widespread decline is evident across Europe since 1980 ([PECBMS 2009](#)).

## YELLOW WAGTAIL

*Motacilla flava*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: red (species level, races *flavissima* and *flava*)

UK Biodiversity Action Plan: priority species

### Long-term trend

UK, England: rapid decline

### UK population size

11,500–26,500 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS and WBS trends:

[BiE04](#), [APEP06](#))

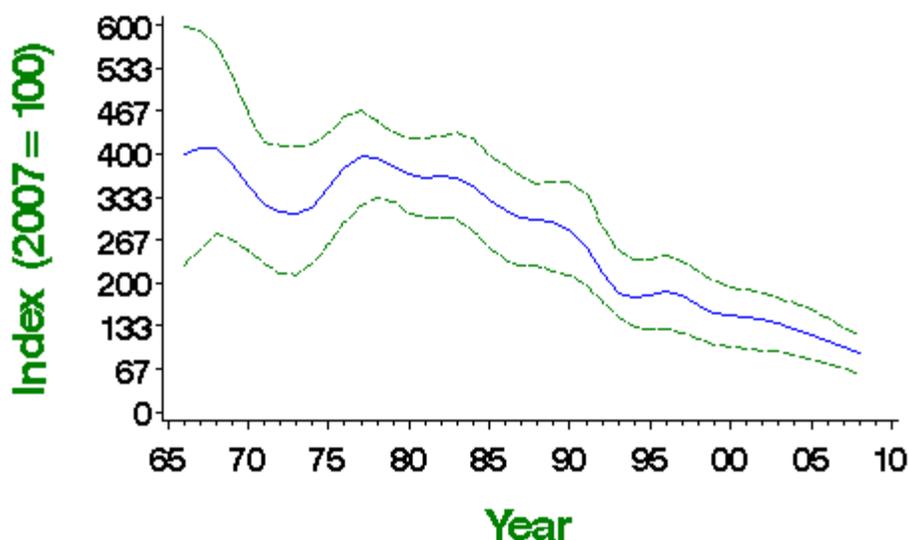

### Status summary

Britain holds almost the entire population of the distinctive race *flavissima*, and so population changes in the UK are of global conservation significance. Yellow Wagtails have been in decline since the early 1980s, according to CBC/BBS and especially WBS/WBBS and, after a shift from the green to the amber list in 2002, the species has now been moved to the red list ([Eaton et al. 2009](#)). [Gibbons et al. \(1993\)](#) identified a range contraction towards a core area in central England, concurrent with the early years of decline. Farmland drainage, the conversion of pasture to arable land, the change from spring to winter cereals, and the loss of insects associated with cattle have been cited as possible causes ([Gibbons et al. 1993](#), [Nelson et al. 2003](#)). Although nest record sample sizes are small, there has been a notable reduction in brood size since the mid 1960s, and the species is listed as of NRS concern ([Leech & Barimore 2008](#)). The European trend, which includes other races of the species, has also been strongly downward since 1980 ([PECBMS 2009](#)).

## GREY WAGTAIL

*Motacilla cinerea*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: amber (25–50% population decline)

### Long-term trend

UK: probable moderate decline

### UK population size

38,400–46,200 pairs in 2000 (1988–91 Atlas estimate updated using CBC and WBS trends: [BiE04](#), [APEP06](#))

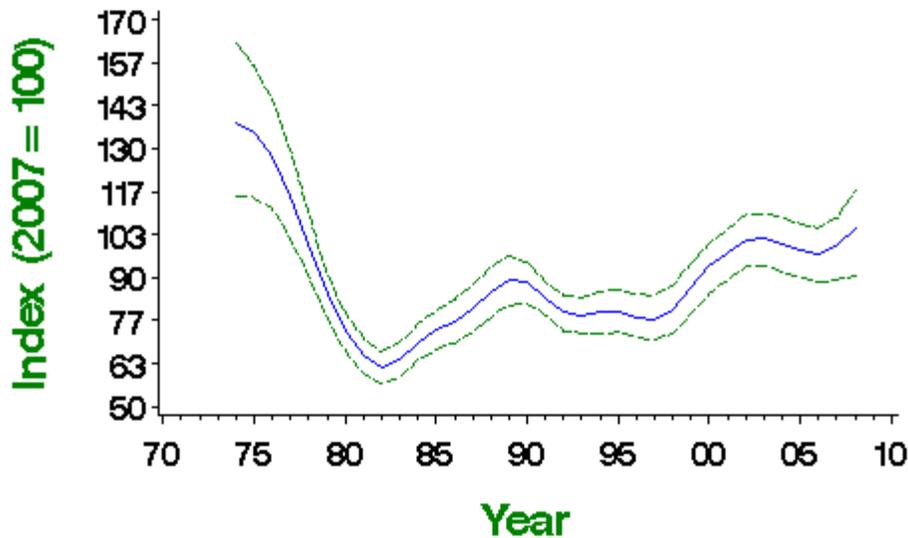

### Status summary

Grey Wagtails occur at highest densities along fast-flowing upland streams. WBS/WBBS shows a fluctuating population size along waterways, with a fall during the late 1970s and early 1980s from an initial high point in 1974, and some increase since the late 1990s. The species was moved from the green to the amber list in 2002, because of a 41% decline recorded between 1975 and 1999, and remains in that category despite substantial population recovery. BBS figures showed an initial ten-year phase of increase, which has now stabilised. The trends for Grey Wagtail are very similar to those for [Pied Wagtail](#), suggesting that similar factors may be affecting these two species. Clutch and brood size of Grey Wagtails rose as the population fell, and are now getting smaller again, raising NRS concern ([Leech & Barimore 2008](#)). Nest failure rates have dropped substantially, and there has been linear increase in the number of fledglings per breeding attempt.

## WBS/WBBS 1974–2008

## PIED WAGTAIL

*Motacilla alba*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: green (species level); amber (race *yarrellii*, >20% of European breeders)

### Long-term trend

UK: uncertain

### UK population size

272,000–352,000 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS and WBS trends:

[BiE04](#), [APEP06](#))

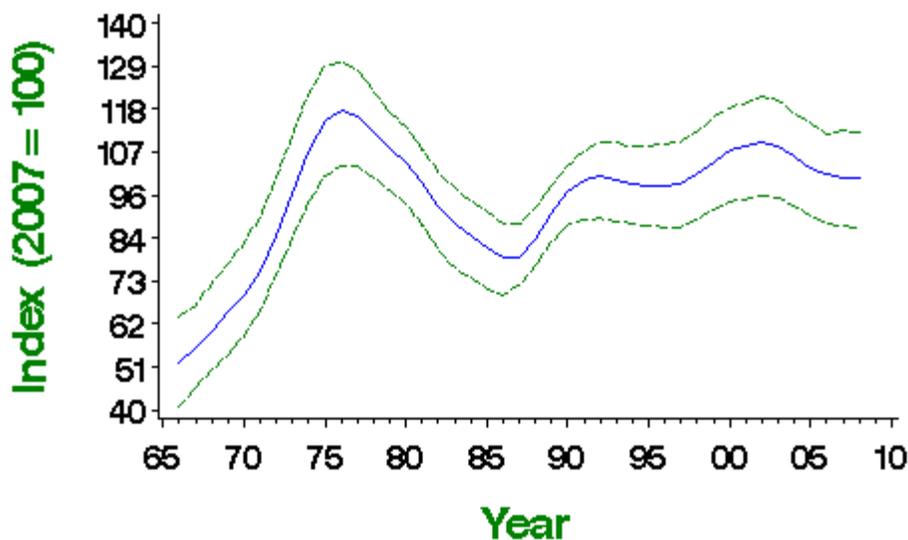

### Status summary

Britain and Ireland together hold almost the entire population of the distinctive dark-backed race *yarrellii*, and for this reason population changes in the UK are of global conservation significance. The CBC shows that a strong increase occurred up to the mid 1970s, such that populations have shown moderate increase overall since 1966. Since 1974, however, the results of monitoring are somewhat conflicting: CBC/BBS and WBS/WBBS trends fluctuate in parallel but, whereas little overall change is evident in the CBC/BBS index, WBS/WBBS has shown a moderate decline, perhaps suggesting the influence of factors specific to linear waterways. The long-term trend in abundance is similar to those shown by [Wren](#) and [Long-tailed Tit](#), two other resident insectivores ([Siriwardena et al. 1998a](#)). Average clutch and brood sizes have declined a little, raising NRS concern ([Leech & Barimore 2008](#)), but this has been counteracted by a large fall in nest failure rates. The number of fledglings per breeding attempt has shown a strong linear increase.

## DIPPER

### *Cinclus cinclus*

- Population changes
- Productivity trends
- Additional information

### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)  
 UK: green (species level); amber (race *gularis*, >20% of European breeders; race *hibernicus*, >20% of European breeders, European status)

### Long-term trend

UK waterways: moderate decline

### UK population size

6,800–20,000 pairs in 2000 (1988–91 Atlas estimate updated using WBS trend: [BiE04](#), [APEP06](#))

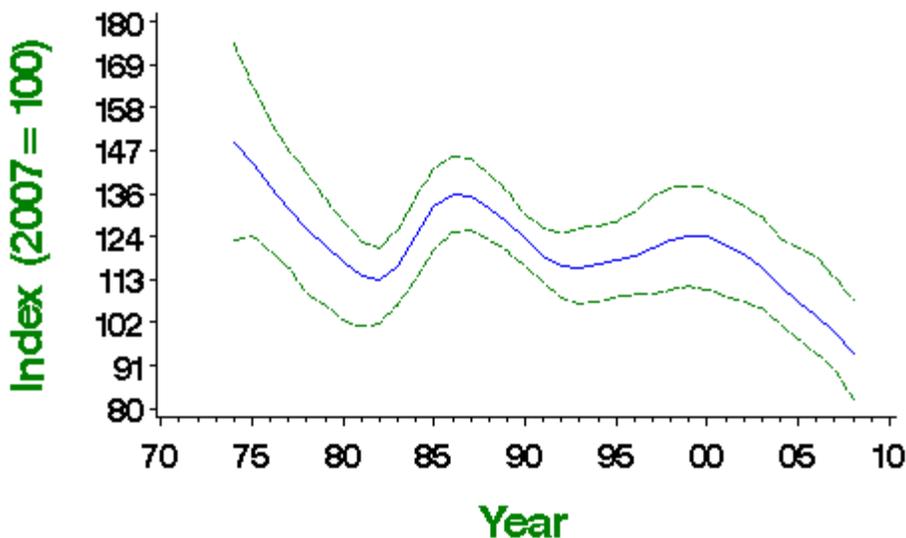

### Status summary

The WBS/WBBS shows that Dipper populations have fluctuated over the last thirty years, but with an overall downward trend. The species is unusually sensitive to acidity and other water pollution ([Ormerod & Tyler 1989, 1990](#)), with lower breeding densities and productivity on acidic than on more neutral streams ([Ormerod et al. 1991, Vickery 1991, 1992](#)). Breeding performance has improved strongly over time, and laying dates have shifted earlier, perhaps because of climate change ([Crick & Sparks 1999](#)). Broods now average larger than in the late 1960s and 1970s, and there has been substantial reduction in failure rates of nests at the egg stage, leading to sustained increase in the number of fledglings per breeding attempt.

## WREN

### *Troglodytes troglodytes*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: green (species level); amber (race *indigenus*, >20% of European breeders; races *hebridensis* and *zetlandicus*, >20% of European breeders, European status); red (races *fridariensis* and *hirtensis*, rare breeders of global importance)

UK Biodiversity Action Plan: priority species (Fair Isle & St Kilda races only)

### Long-term trend

UK: rapid increase

England: moderate increase

### UK population size

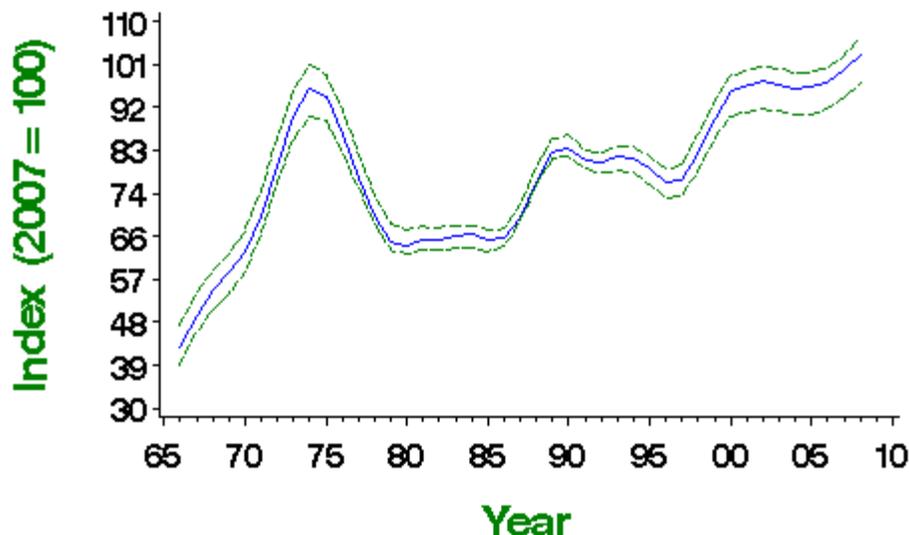

8,512,000 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

### Status summary

The Wren's current UK population estimate is the highest for any species. Abundance can vary sharply from year to year in this species, however, although this is not evident from the smoothed trends presented here. Annual numbers are influenced by mortality rates that may be very high in severe winters and by the species' high breeding potential ([Peach et al. 1995b](#)). Wren numbers in the UK were greatly depleted by the cold winter of 1962/63 ([Marchant et al. 1990](#)). Following a rapid recovery up to the mid 1970s, abundance fell again in response to a further series of cold winters only to return to its previous high level. BBS results suggest that increase since 1994 has been much stronger in Scotland and Northern Ireland than in Wales and England. Rather fewer nests are now failing at the egg stage, but there has been no trend in the number of fledglings per breeding attempt. Numbers have risen widely in Europe since 1980 ([PECBMS 2009](#)).

## ROBIN

*Erithacus rubecula*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (concentrated in Europe, conservation status favourable)

UK: green

### Long-term trend

UK: shallow increase

England: moderate increase

### UK population size

5,895,000 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

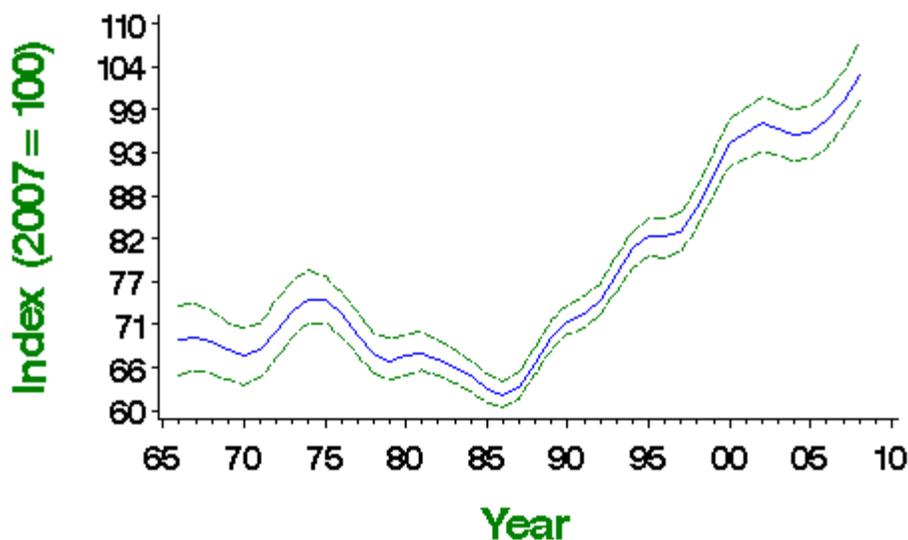

### Status summary

Robins have increased markedly since the mid 1980s, according to both CBC/BBS and CES results, having been set back earlier by a succession of cold winters. Steep improvements have occurred concurrently in the numbers of fledglings per breeding attempt, as measured by nest record data, due to reductions in nest failure rates at both egg and chick stages, although CES productivity measures have declined. Survival rates, as measured by CES, may perhaps show an increasing trend. The CES and BBS data show that marked and significant annual fluctuations occur in numbers, perhaps in response to winter weather, although these are not evident in the smoothed trends that are presented. Laying dates have advanced by almost a week since the 1960s. A shallow increase has been evident widely across Europe since 1980 ([PECBMS 2009](#)).

## NIGHTINGALE

### *Luscinia megarhynchos*

• Population changes

• Productivity trends

• Additional information

#### Conservation listings

Europe: no SPEC category (concentrated in Europe, conservation status favourable)

UK: amber (25–50% distribution decline)

#### Long-term trend

UK: probable decline

#### UK population size

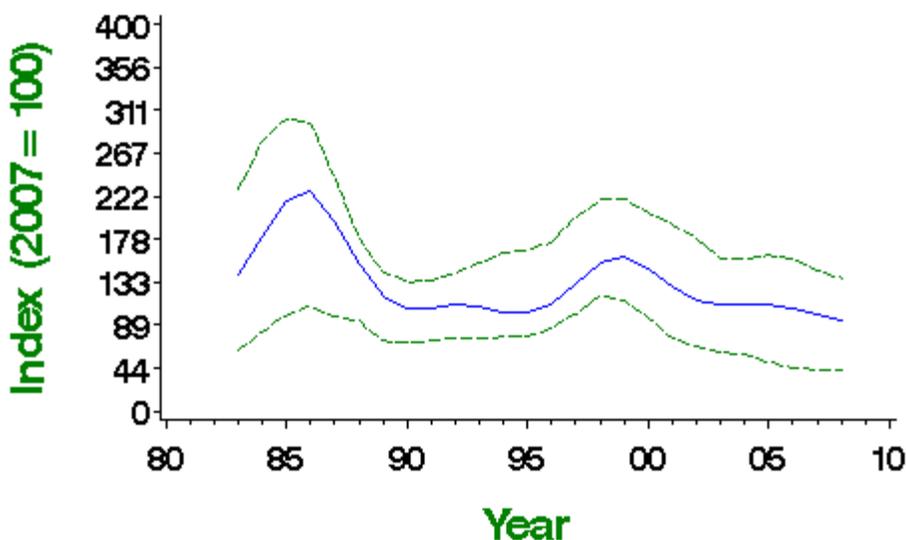

6,700 (5,600–9,350) males in 1999 ([Wilson et al. 2002](#); [BiE04](#), [APEP06](#))

#### Status summary

In 1999, the BTO organised a national survey of Nightingales, which showed a marked range contraction since the previous survey in 1980, but only an 8% overall population decline ([Wilson et al. 2002](#); for more details [click here](#)). Nightingales are scarce birds, and CBC and BBS data are correspondingly meagre. Nevertheless, analysis of the available CBC data shows continuous decline (G.M. Siriwardena, unpubl.) and CES suggests a probable decline. [Fuller et al. \(2005\)](#) suggest the likely causes of Nightingale decline relate to pressures on migration and in winter, perhaps compounded by habitat loss in Britain. The increasing intensity of browsing by deer is known to reduce habitat quality for this species ([Gill & Fuller 2007](#)). CES indicates a sharp decline in productivity during the 1980s, perhaps because Nightingale nesting success may be adversely affected by cold and wet springs. Nightingale is one of the most strongly declining bird species in Europe, having decreased at an annual rate of 4% during 1980–2005; this overall figure masks a contrast between severe decreases in southern and western Europe and strong increases in the east of the range ([PECBMS 2007, 2009](#)).

## REDSTART

### *Phoenicurus phoenicurus*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: SPEC category 2 (depleted)

UK: amber (European status)

### Long-term trend

UK, England: shallow decline

### UK population size

At least 101,000 pairs in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

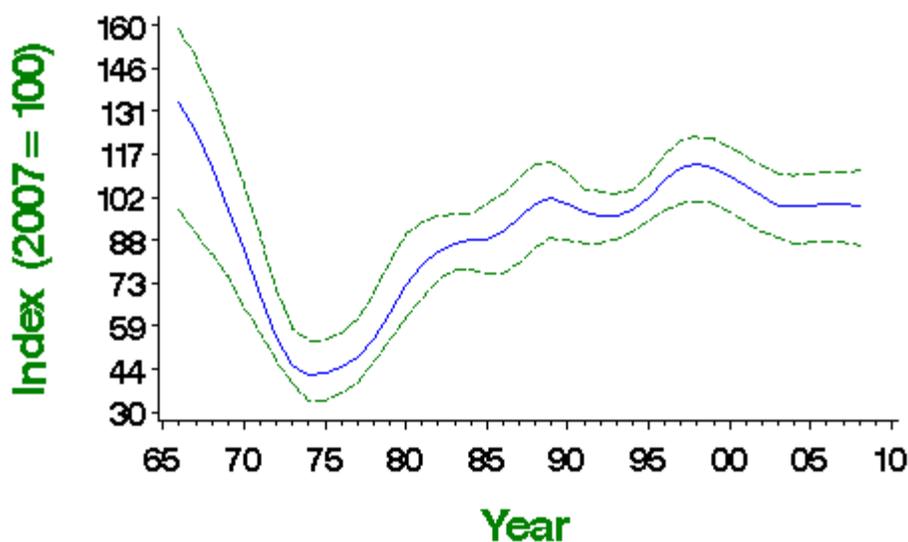

### Status summary

The decline in the late 1960s and early 1970s was thought to be due to severe drought conditions in the Sahel wintering area in Africa ([Marchant \*et al.\* 1990](#)). There was a loss of range of 20% in Britain between 1968–72 and 1988–91, in terms of the numbers of occupied 10-km squares ([Gibbons \*et al.\* 1993](#)). A recovery in population size began in the mid 1970s and appears to have continued, at least in England, into the late 1990s. This increase has been associated with steeply improving numbers of fledglings per breeding attempt and progressively earlier laying dates. The trend towards earlier laying can be partly explained by recent climate change ([Crick & Sparks 1999](#)).

## WHINCHAT

### *Saxicola rubetra*

- Population changes
- Productivity trends
- Additional information

#### Conservation listings

Europe: no SPEC category (concentrated in Europe, conservation status favourable)  
 UK: amber (25–50% decline)

#### Long-term trend

UK: decline

#### UK population size

14,000–28,000 pairs in 1990 (1988–91 Atlas: [APEP06](#));  
 11,000–22,100 pairs in 2000 (updated using BBS trend: [BiE04](#))

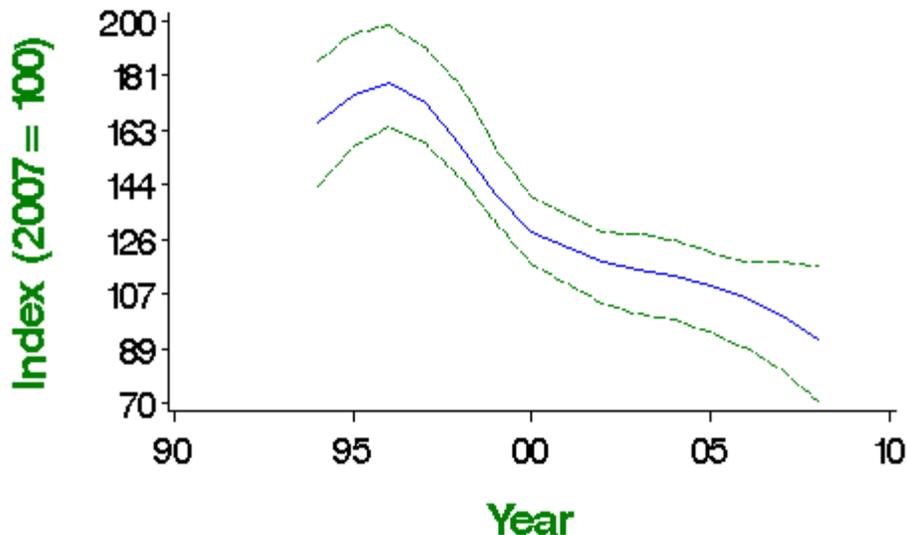

#### Status summary

Whinchats were not monitored until the BBS began in 1994. By then, however, [Gibbons \*et al.\* \(1993\)](#) had already identified a major range contraction, mainly from lowland England, that was probably at least partly due to the loss of marginal farmland habitats ([Marchant \*et al.\* 1990](#)). Further extinctions have occurred since then among the remaining pockets of lowland breeders. BBS data indicate that further strong population decline took place during the 1990s, raising BTO alerts for the UK as a whole as well as for England. Nest record samples are small, but indicate substantial recent rises in nest losses at the egg and chick stages, which are of NRS concern ([Leech & Barimore 2008](#)). Whinchats are estimated to have declined by 2% per year across Europe during 1980–2006 ([PECBMS 2009](#)). On the strength of its UK decline, Whinchat has recently been moved from the green to the amber list of conservation concern ([Eaton \*et al.\* 2009](#)).

## STONECHAT

*Saxicola torquatus*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: green

### Long-term trend

UK: uncertain, possible decline

### UK population size

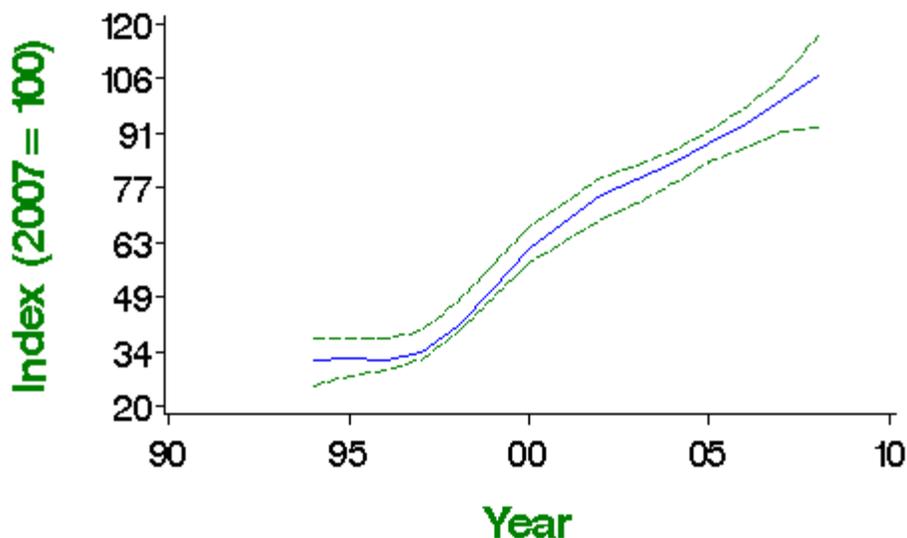

9,000–23,000 pairs in 1990 (1988–91 Atlas: [APEP06](#)); 19,300–49,400 pairs in 2000 (updated using BBS trend: [BiE04](#))

### Status summary

Trends were poorly quantified before the start of the BBS, but a long-term decline is suspected: severe winter weather, and loss and fragmentation of suitable breeding habitat in many inland regions, are believed to have reduced the population from the 1940s onward ([Marchant et al. 1990](#)). Breeding atlas data showed a substantial contraction in the Stonechat's range between the early 1970s and late 1980s ([Gibbons et al. 1993](#)). Nest failure rates have fallen markedly over the long term, and the numbers of fledglings per breeding attempt have risen steeply. Against this background, the current, strongly increasing BBS trend represents substantial and possibly even complete recovery. Following similar increases widely across Europe, the species is now provisionally categorised as 'secure' ([BirdLife International 2004](#)) and consequently the species has recently been moved from the amber to the green list in the UK ([Eaton et al. 2009](#)).

## WHEATEAR

### *Oenanthe oenanthe*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: SPEC category 3 (declining)

UK: amber (species level and race *oenanthe*, European status)

### Long-term trend

UK: possible decline

### UK population size

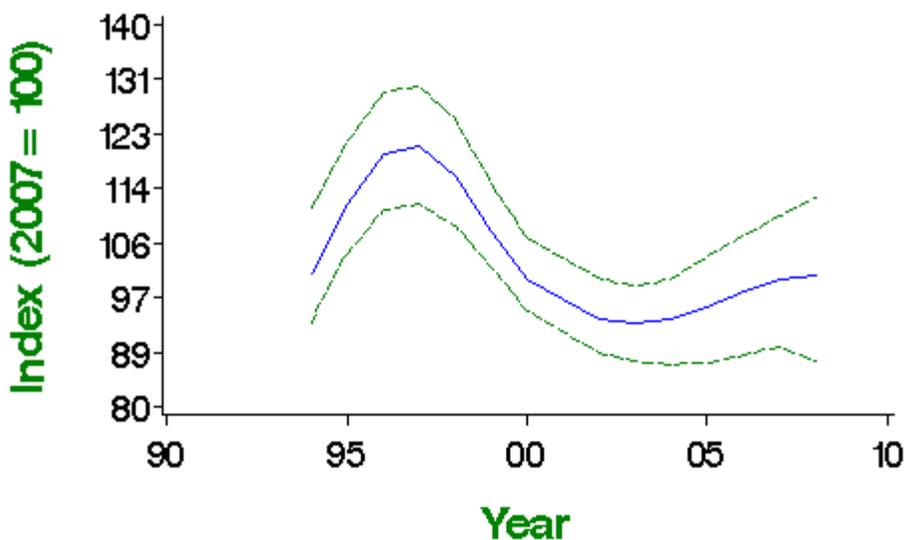

56,000 pairs in 1990 (1988–91 Atlas: [APEP06](#)); 52,500 pairs in 2000 (updated using BBS trend: [BiE04](#)); 100,000–200,000 pairs in Britain ([Sellers 2006](#))

### Status summary

Although it is a common breeding species in many upland areas, the Wheatear was not monitored at the UK scale until the BBS began in 1994. [Gibbons et al. \(1993\)](#) had by then identified range contractions from lowland Britain since 1968–72, perhaps due to losses of suitable grassland and declines in rabbit abundance. BBS shows wide fluctuations, with further decrease in England and Wales, but as yet no clear trend in abundance since 1994 in Scotland. BBS data indicate that the estimates of UK population made for the 1988–91 Atlas may have been far too low, possibly by an order of magnitude ([Gillings et al. 2007](#)). Failure rates at the egg stage (18 days, comprising 14 days incubation and 4 days laying) have fallen substantially. Wheatear is one of the most strongly declining bird species in Europe, having decreased at an annual rate of 4% during 1980–2006 ([PECBMS 2009](#)). Following widespread declines across Europe during the 1990s, the European status of this species is no longer considered 'secure' ([BirdLife International 2004](#)). Accordingly, the species has recently been moved from the green to the amber list in the UK ([Eaton et al. 2009](#)).

**RING OUZEL***Turdus torquatus*

• Population changes

• Productivity trends

• Additional information

**Conservation listings**

Europe: no SPEC category (concentrated in Europe, conservation status favourable)

UK: red (>50% population decline)

UK Biodiversity Action Plan: priority species

**Long-term trend**

UK: probable decline

**UK population size**

6,157–7,549 pairs in 1999 ([Wotton et al. 2002: BiE04, APEP06](#))

**Status summary**

The first breeding atlases showed a decline of 27% in the number of 10-km squares occupied between 1968–72 and 1988–91 ([Gibbons et al. 1993](#)), and the extent of population decline has since been established by a special survey: a 58% population decline was estimated for the period between 1988–91 and 1999, warranting red listing for this species ([Gregory et al. 2002](#)). British & Irish bird observatory data show a decline in spring passage Ring Ouzels at western locations during 1970–98 that matches the estimated UK breeding decline, but no decline at eastern observatories where most birds are of Fennoscandian origin ([Burfield & Brooke 2005](#)). These authors infer that, since these populations winter together, the reasons for decline among UK breeders must lie on the breeding grounds or on passage: they also point out that UK birds are more exposed to hunting pressures, particularly in southwest France. It has proved difficult to establish any reasons for decline that are linked to the breeding grounds ([Buchanan et al. 2003](#)). In southeast Scotland, however, the breeding sites that are still occupied tend to be those at higher altitude and that have retained an extensive cover of heather ([Sim et al. 2007b](#)). In the same study, it was shown that declines were greatest in years following warm summers on the breeding grounds and also greater two years after high spring rainfall in Morocco: these results suggest that the population decline could be linked to reduced food supplies, and consequently higher rates of natural mortality, in autumn and winter ([Beale et al. 2006](#)).

## BLACKBIRD

*Turdus merula*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (concentrated in Europe, conservation status favourable)

UK: green

### Long-term trend

UK, England: shallow decline

### UK population size

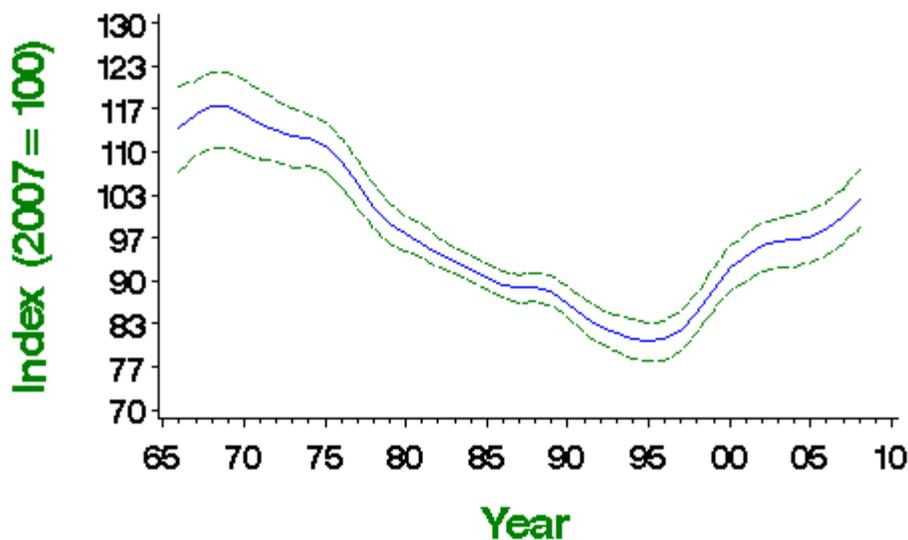

4,935,000 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

### Status summary

Both CBC/BBS and CES data show long-term declines in Blackbird abundance, but recent increases indicate that the population has begun to recover. The moderate-decline criteria for amber listing and for BTO alerts are no longer met, and the species has been listed in the green category since 2002. CBC results show that the decline began in the mid 1970s. It is likely that reduced survival drove the decline ([Siriwardena et al. 1998a](#)), although there has been no change in survival as recorded by CES since 1983. Fledglings per breeding attempt also show no change. Agricultural intensification is likely to have contributed ([Fuller et al. 1995](#)), but, since numbers fell in woodland as well as farmland, additional factors probably operated.

## SONG THRUSH

*Turdus philomelos*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (concentrated in Europe, conservation status favourable)

UK: red (species level, races *clarkei* and *hebridensis*)

UK Biodiversity Action Plan: [click here](#)

### Long-term trend

UK, England: moderate decline

### UK population size

1,144,000 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

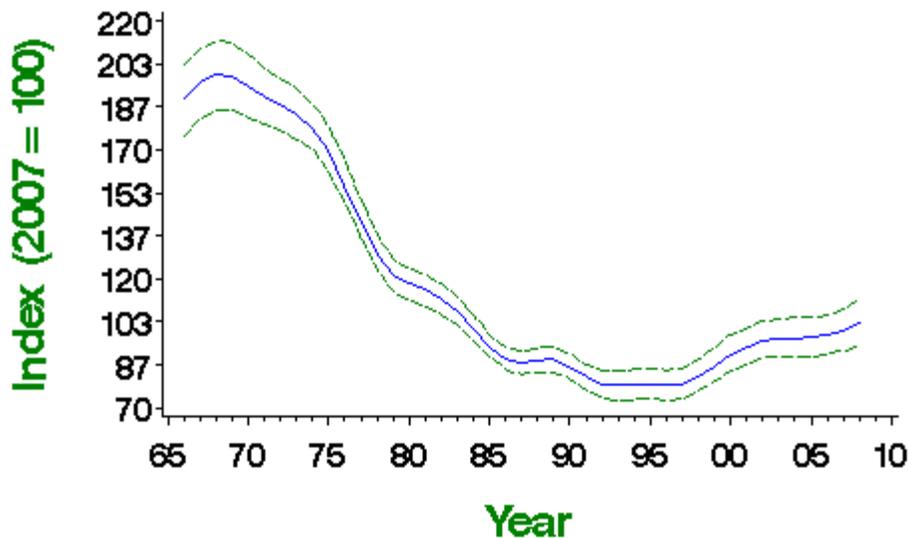

### Status summary

CBC/BBS shows a rapid decline in Song Thrush abundance that began in the mid 1970s. The second half of this decline can also be seen in the CES index. CES productivity showed an initial decrease, followed by some partial recovery, and NRS data indicate that productivity may have improved since 1981. Changes in survival in the first winter, and perhaps also the post-fledging period, are sufficient to have caused the population decline ([Thomson et al. 1997](#), [Siriwardena et al. 1998a](#), [Robinson et al. 2004](#)). The environmental causes of these changes are not known, but changes in farming practices, land drainage, pesticides and predators are all possible contributors ([Fuller et al. 1995](#), [Robinson et al. 2004](#)). In woodland, drainage of damp ground and the depletion of woodland shrub layers through canopy closure and deer browsing may also be implicated ([Fuller et al. 2005](#)). Recent CBC/BBS data show a general increase, but population levels remain relatively low. Recovery of rural Song Thrush populations requires challenging new policy initiatives that should aim to restore nesting cover in scrub and woodland understorey, grazed grassland in arable-dominated areas, and damper soils in summer ([Peach et al. 2004](#)).

## MISTLE THRUSH

*Turdus viscivorus*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (concentrated in Europe, conservation status favourable)

UK: amber (25–50% population decline)

### Long-term trend

UK, England: moderate decline

### UK population size

222,500 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

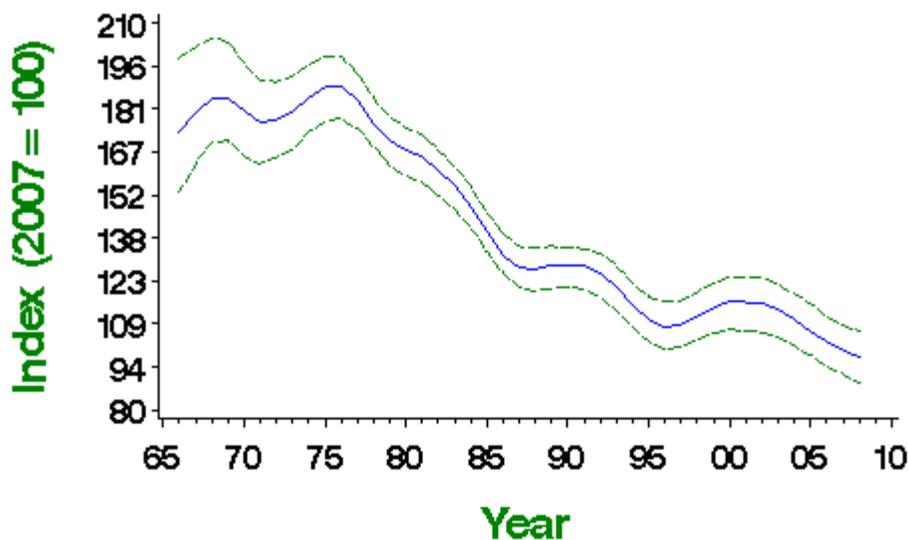

### Status summary

Like those of [Song Thrush](#) and [Blackbird](#), Mistle Thrush populations have declined significantly since the mid 1970s, especially on farmland. The species was recently moved from the green to the amber list because of population decline, and recent BBS data suggest that this decline is continuing. The Scottish BBS trend, in contrast to those elsewhere in the UK, is of strong increase since the late 1990s. There has been linear increase in the number of fledglings per breeding attempt, and a minor increase in clutch size; population decline is thus likely to have been driven by reduced annual survival ([Siriwardena et al. 1998](#)). Numbers have fallen widely in Europe since 1980 ([PECBMS 2009](#)).

## CETTI'S WARBLER

*Cettia cetti*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: green

### Long-term trend

England, Wales: increase

### UK population size

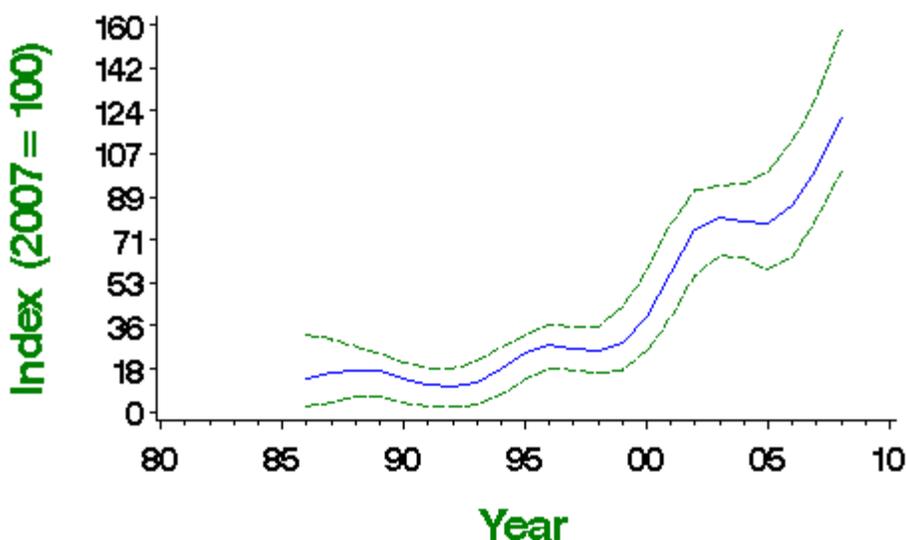

534 pairs in 1997–2001 (RBBP data: [BiE04](#)); mean of 645 pairs in 1998–2002 (RBBP data: [APEP06](#)); at least 2,024 singing males or territories in 2007 ([Holling & RBBP 2010](#))

### Status summary

Cetti's Warblers were first recorded in Britain as recently as 1961. Colonisation, which began in Kent in 1972 or 1973, continues to be monitored annually by [RBBP](#). Numbers and breeding range increased spectacularly during the first 12 years, with Norfolk and Dorset gradually overtaking Kent as the main host counties ([Gibbons \*et al.\* 1993](#), [Wotton \*et al.\* 1998](#)). Severe winters after 1978 led to the temporary extinction of the Kent population in 1988. Populations in milder regions continued to grow, but overall the UK population fell by over a third between 1984 and 1986. In the absence of severe winters since 1986, increase and range expansion have continued. The first breeding records north of the Humber were made in 2006 ([Holling & RBBP 2009](#)). Much constant-effort ringing takes place in prime Cetti's Warbler habitat; despite the comparative rarity of this species, therefore, CES population and productivity indices are already available ([Robinson \*et al.\* 2007](#)). CES data confirm the species' sensitivity to cold winters, which appears to have become more evident as the breeding range has expanded into more testing climates. Numbers have risen widely in Europe since 1990 ([PECBMS 2009](#)).

### CES adult abundance 1986–2008

#### Cetti's Warbler

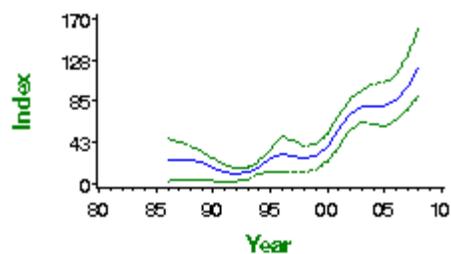

**1997-2007: 280% (confidence interval 128% to 702%)**

## GRASSHOPPER WARBLER

*Locustella naevia*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (concentrated in Europe, conservation status favourable)

UK: red (>50% population decline)

UK Biodiversity Action Plan: priority species

### Long-term trend

UK: rapid decline

### UK population size

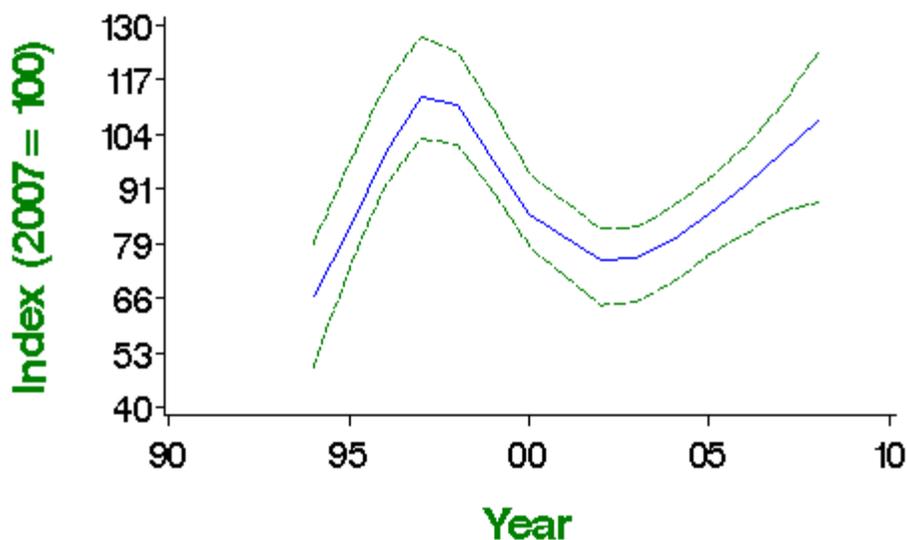

11,750 pairs in 1990 (1988–91 Atlas: [APEP06](#)); 12,300 pairs in 2000 (updated using BBS trend: [BiE04](#))

### Status summary

Grasshopper Warbler was previously amber-listed because of a contraction in range during the period preceding the 1988–91 Atlas, reportedly due to habitat loss ([Gibbons \*et al.\* 1993](#)). The CBC index suffered from small and severely dwindling sample sizes, but the available data indicate a rapid population decline between the mid 1960s and mid 1980s, when numbers became too small for annual monitoring ([Marchant \*et al.\* 1990](#)). On this basis, the species is now red-listed. The BBS shows wide fluctuations in abundance since 1994, and currently an overall shallow increase. Given suitable habitat and conditions, the species has high reproductive potential, as demonstrated by analysis of nest record data ([Glue 1990](#)). Numbers have fallen widely in Europe since 1980 ([PECBMS 2009](#)).

## SEDGE WARBLER

### *Acrocephalus schoenobaenus*

- Population changes
- Productivity trends
- Additional information

#### Conservation listings

Europe: no SPEC category (concentrated in Europe, conservation status favourable)

UK: green

#### Long-term trend

UK: shallow decline

England: moderate decline

#### UK population size

321,000 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

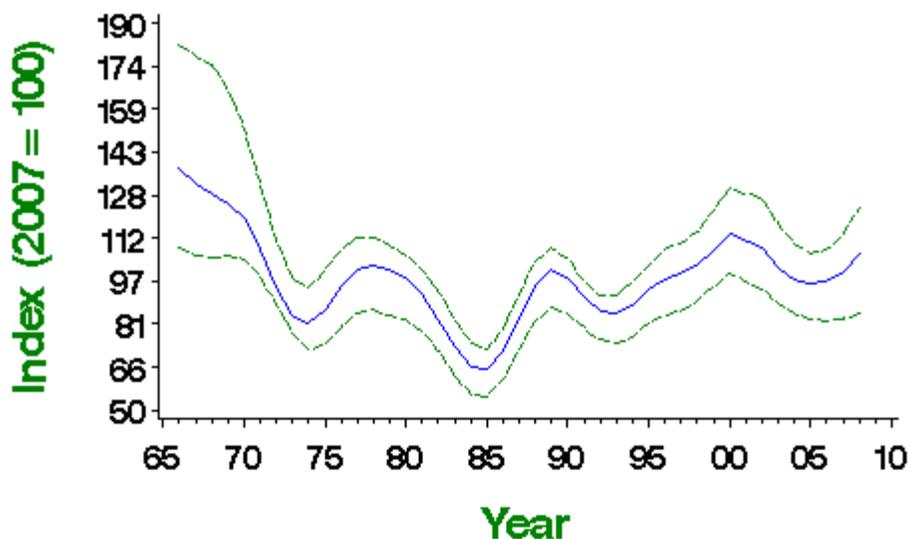

#### Status summary

The trend in England is apparently of moderate decline, but this is uncertain because the long-term changes are partly obscured by shorter fluctuations in numbers. Detailed analysis of BTO data sets has shown that much of the year-to-year variation in population size is driven by changes in adult survival rates which, in turn, are related to changes in rainfall on their wintering grounds, just south of the Sahara Desert, in the West African Sahel ([Peach et al. 1991](#)). The smoothed CBC/BBS and WBS/WBBS trends show four troughs in population, related to years of poor West African rainfall, with a low point in 1984–85. The CES, which provides the biggest Sedge Warbler sample, shows the most recent three of the same troughs. Daily nest failure rates at the egg stage have halved, and the numbers of fledglings per breeding attempt has shown linear increase. CES productivity data show a sustained decrease since the late 1980s.

## REED WARBLER

### *Acrocephalus scirpaceus*

- Population changes
- Productivity trends
- Additional information

#### Conservation listings

Europe: no SPEC category (concentrated in Europe, conservation status favourable)

UK: green

#### Long-term trend

UK: probable increase

#### UK population size

60,800–122,000 pairs in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

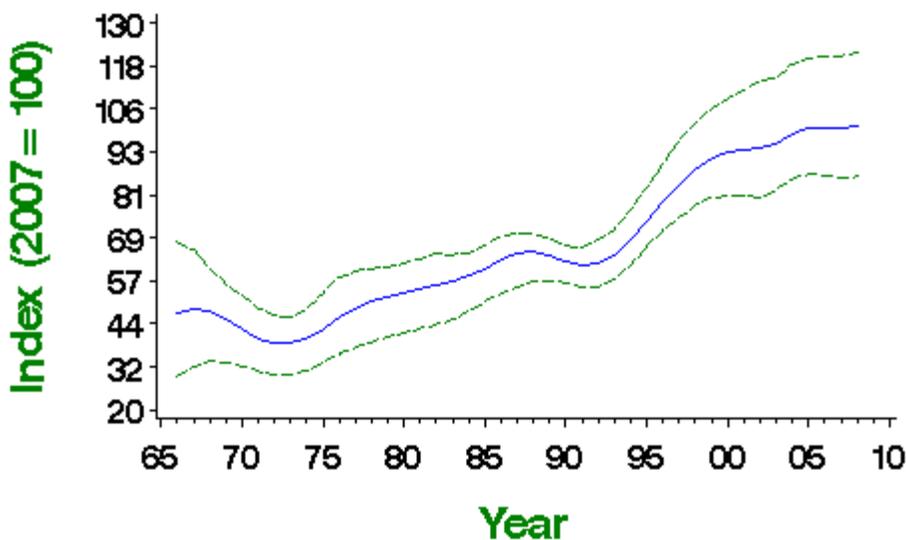

#### Status summary

This species has an unusually clumped distribution, with very high breeding concentrations in *Phragmites* reedbeds, where numbers are very hard to census. Because of this, CES, which has many sites in reedbeds, ought perhaps be a better measure of population change than either CBC/BBS or WBS/WBBS, where the species is encountered mainly at low density or in linear habitats. CES shows a decline from 1983 until the early 1990s, followed by a partial recovery, and another more recent decline. Both CBC/BBS and WBS/WBBS show progressive moderate increases, however, perhaps linked to increasingly sensitive management of small and linear wetland sites. Population increase, as indicated by the census work, accords with the remarkable range expansion the species has achieved since the 1960s, as recorded by [atlas projects](#). West Wales, northwest and northeast England were colonised, as was the east coast of Ireland, between 1968–72 and 1988–91 ([Gibbons et al. 1993](#)), and the species is now regular as far north as the Tay reedbeds ([Robertson 2003](#)). Breeding performance as measured by brood size and failure rates has improved slightly; there has been linear increase in the numbers of fledglings per breeding attempt, and a small improvement is apparent in CES productivity. The trend towards earlier laying can be partly explained by recent climate change ([Crick & Sparks 1999](#)).

## BLACKCAP

*Sylvia atricapilla*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (concentrated in Europe, conservation status favourable)

UK: green

### Long-term trend

UK, England: rapid increase

### UK population size

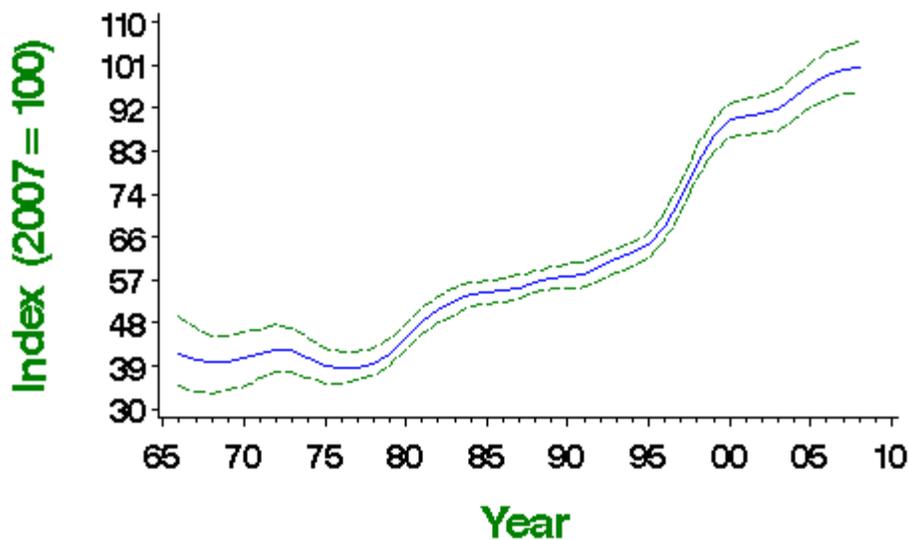

932,000 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

### Status summary

Blackcap abundance has increased consistently since the late 1970s, a trend common to all habitats and evident from both the CBC/BBS and the CES indices, although the causes remain unknown. There have been no clear accompanying trends in productivity or survival. The trend towards earlier laying may be a response to recent climate change ([Crick & Sparks 1999](#)). The more rapid increase in Scotland indicated by BBS suggests that climatic warming may be allowing this species to spread its range northwards. Numbers have risen widely across Europe since 1980 ([PECBMS 2009](#)).

## GARDEN WARBLER

*Sylvia borin*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (concentrated in Europe, conservation status favourable)

UK: green

### Long-term trend

UK, England: shallow decline

### UK population size

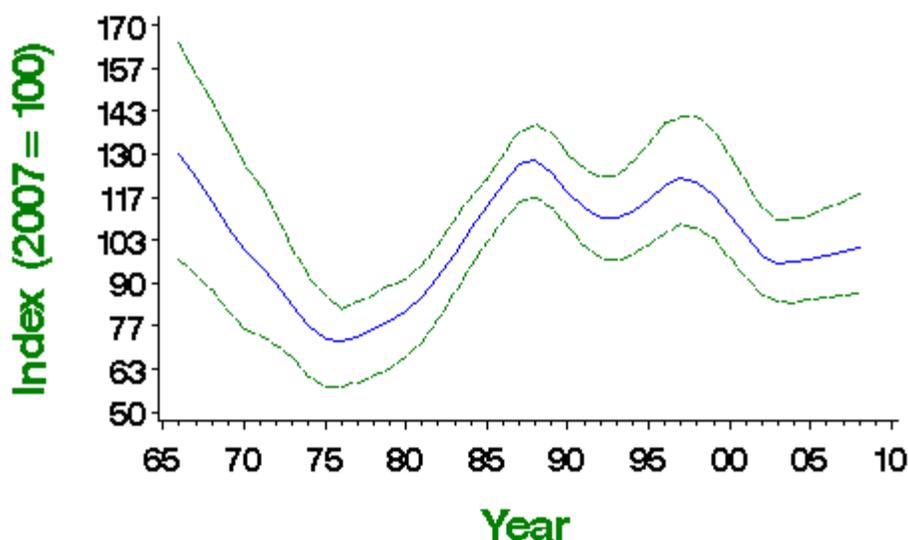

190,000 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

### Status summary

Garden Warbler abundance has varied alongside that of other trans-Saharan migrant warblers ([Siriwardena et al. 1998b](#)), probably reflecting the influence of changes in their winter environment. Despite large short-term fluctuations in abundance, the CBC/BBS and CES now both suggest that the population is in long-term decline. There has been no change in fledglings per breeding attempt or in CES survival rates, but post-fledging productivity, as measured by the CES, has declined sharply since 1983. Numbers have shown widespread moderate decline across Europe since 1980 ([PECBMS 2009](#)).

### CBC/BBS UK 1966–2008 Garden Warbler

1967-2007: -19% (confidence interval -43% to 28%)

## LESSER WHITETHROAT

*Sylvia curruca*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: green

### Long-term trend

UK, England: fluctuating, with no long-term trend

### UK population size

64,000 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

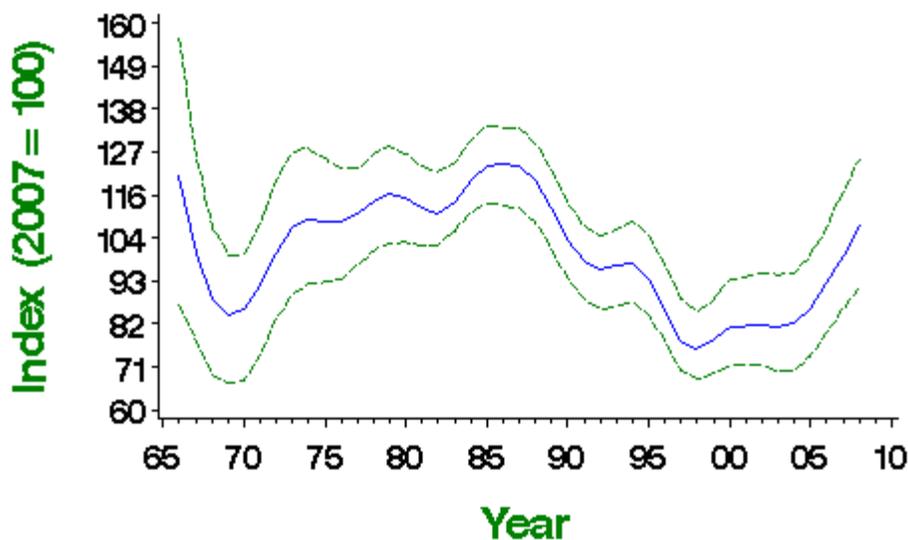

### Status summary

Lesser Whitethroat abundance was roughly stable (albeit with short-term fluctuations) from the 1960s until the late 1980s, but the CBC/BBS and CES trends provide evidence for a subsequent moderate decline that lasted into the late 1990s. These changes were statistically significant, and large enough over the relevant periods to trigger BTO alerts. BBS has subsequently shown a significant sharp upturn, but this contrasts strongly with the continued decrease recorded by CES ringers. Wide fluctuations in survival and productivity have been recorded by CES ringers, and may be influencing population change, but pressures during migration and in winter are the most likely causes of decline ([Fuller et al. 2005](#)).

## WHITETHROAT

*Sylvia communis*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (concentrated in Europe, conservation status favourable)

UK: amber (25–50% decline, 1969–2006)

### Long-term trend

UK, England: rapid decline, followed by shallow increase

### UK population size

945,000 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

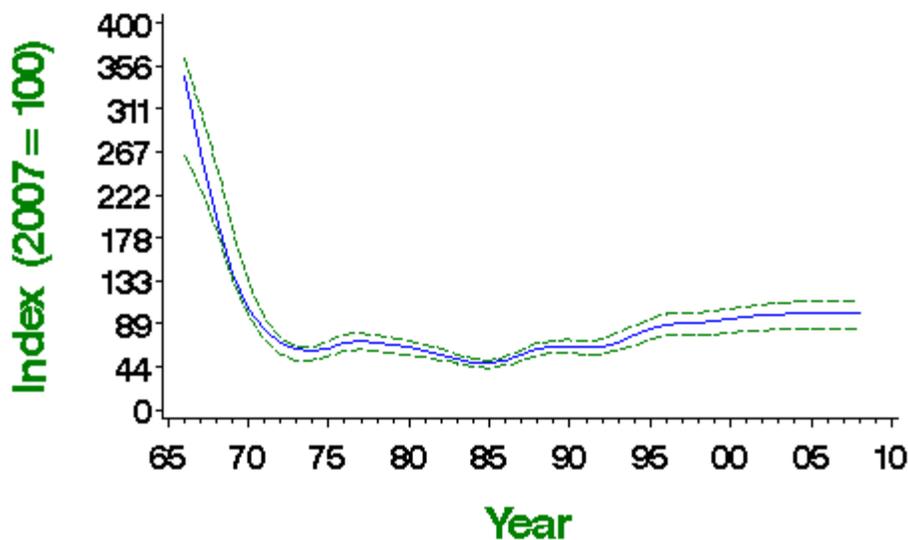

### Status summary

Whitethroat populations had been stable for a few years up to 1968 but, despite a normal departure for their wintering grounds in West Africa, crashed by around 70% between the 1968 and 1969 breeding seasons. They fluctuated around their lower level until the mid 1980s, since when they have sustained a consistent shallow recovery. Recovery has been most apparent along linear waterways. In a pioneering study, [Winstanley \*et al.\* \(1974\)](#) linked the 1969 crash to droughts in the Whitethroat's wintering grounds in the western Sahel, just south of the Sahara Desert. Annual fluctuations in abundance, which are not shown in the smoothed trends presented here, correlate to those in overwinter survival ([Baillie & Peach 1992](#)). Other trans-Saharan migrant warblers have shared similarly timed changes in abundance ([Siriwardena \*et al.\* 1998b](#)). There has been no trend in the number of fledglings per breeding attempt. Productivity, as measured by CES, rose during the 1980s and has since fluctuated and fallen back. It seems likely that habitat loss since the 1960s, particularly on farmland, will eventually limit the degree of recovery. A shallow upturn has been detected widely across Europe since 1980 ([PECBMS 2009](#)). The limited extent of UK recovery, coupled with change in the [BoCC](#) criteria, has resulted in the species moving from the green to the amber list at the latest review ([Eaton \*et al.\* 2009](#)).

## WOOD WARBLER

### *Phylloscopus sibilatrix*

- Population changes
- Productivity trends
- Additional information

### Conservation listings

Europe: SPEC category 2 (declining)

UK: red

UK Biodiversity Action Plan: priority species

### Long-term trend

UK: decline

### UK population size

17,200 (15,830–18,570) males in 1984–85 ([Bibby 1989](#); [APEP06](#)); 9,000–10,500 pairs in 2000 (updated using BBS trend: [BiE04](#))

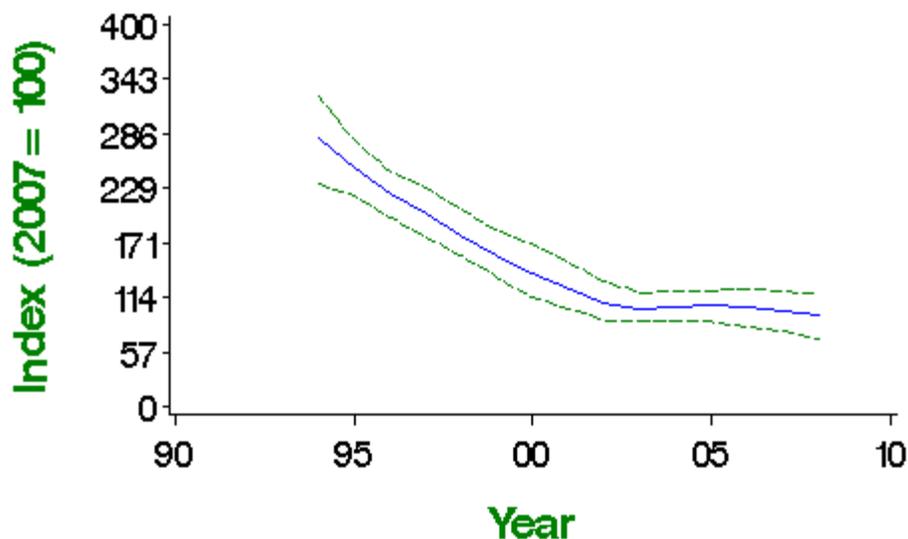

### Status summary

Wood Warblers, which have a westerly distribution in Britain, were monitored relatively poorly until BBS began. Little change was evident at the few CBC plots on which the species occurred ([Marchant et al. 1990](#), [Crick et al. 1998](#)). The species' breeding range varied little between the two atlas periods ([Gibbons et al. 1993](#)), but has subsequently retreated heavily from lowland England. BBS shows a rapid and significant decline since 1994, and accordingly the species was moved from the green to the amber list in 2002; continued decline has now warranted a further shift to the red list. Nest success has apparently improved considerably at the egg stage, although nest record samples are small. There has been no trend in the number of fledglings per breeding attempt. Numbers have fallen widely in Europe since 1980 ([PECBMS 2009](#)). With declines evident across northern and western Europe, this previously 'secure' species is now provisionally categorised as 'declining' ([BirdLife International 2004](#)).

## CHIFFCHAFF

*Phylloscopus collybita*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: green

### Long-term trend

UK, England: shallow increase

### UK population size

807,000 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

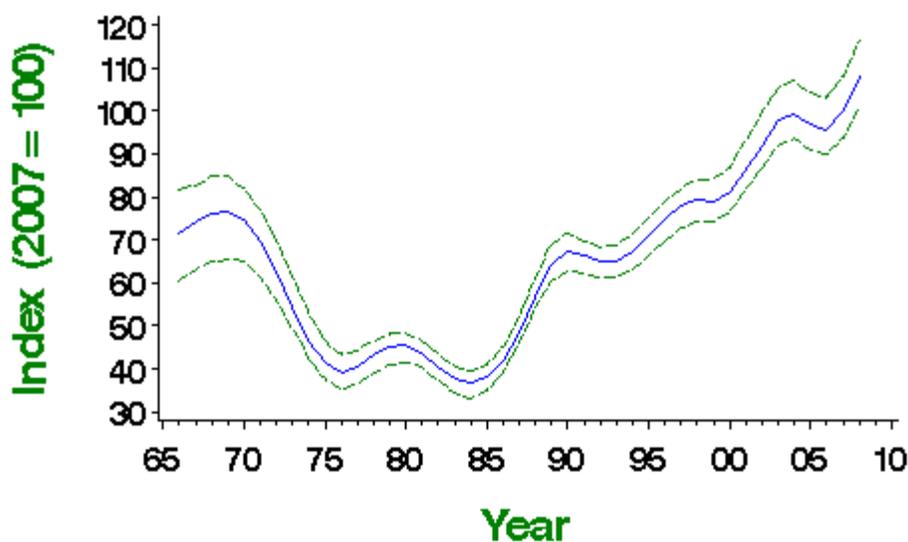

### Status summary

Chiffchaff abundance crashed in the late 1960s/early 1970s in common with that of other trans-Saharan warblers ([Siriwardena et al. 1998a](#)). After remaining stable for a decade, the population recovered strongly, and has continued to increase. This recovery is evident from both CBC/BBS and CES data. Climate change may partly explain the strong trend towards earlier laying ([Crick & Sparks 1999](#)). Overwinter survival may be the critical factor responsible for changes in abundance, as it is for [Whitethroat](#) and [Sedge Warbler](#). Productivity as measured by CES has decreased as the population has risen, but there has been no change in fledglings per breeding attempt or in CES survival. Numbers have risen widely in Europe since 1980 ([PECBMS 2009](#)).

## WILLOW WARBLER

### *Phylloscopus trochilus*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: amber (species level, 25–50% population decline; race *trochilus*, 25–50% population decline, European status)

### Long-term trend

England: rapid decline

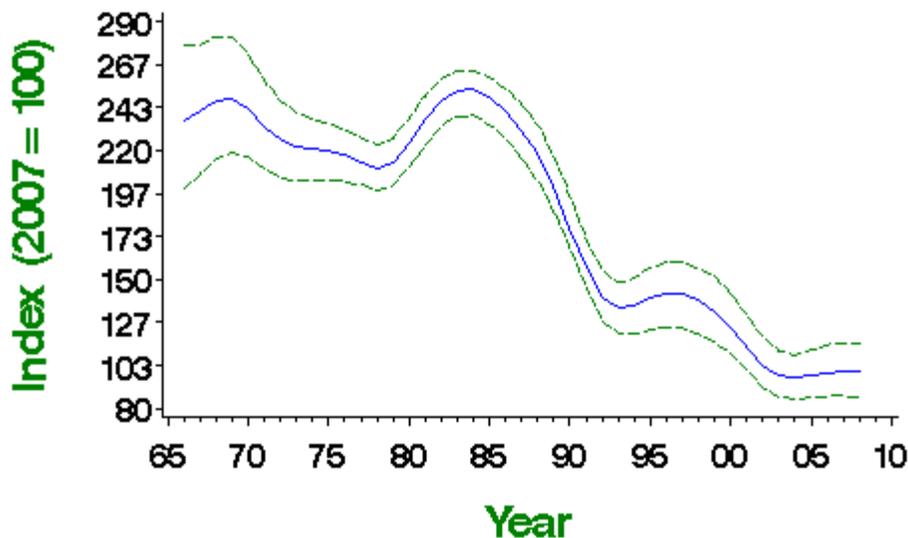

### UK population size

2,125,000 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

### Status summary

Willow Warbler abundance has apparently shown different trends at different UK latitudes. The overall CBC/BBS trend shows a rapid decline during the 1980s and early 1990s, after 20 years of relative stability, and, on the strength of a 31% decline on CBC plots between 1974 and 1999, the species was moved from the green to the amber list. This decline occurred mainly in southern Britain, however, accompanied by a fall in survival rates there ([Peach \*et al.\* 1995a](#)), with Scottish populations remaining unaffected. BBS figures since 1994 indicate a stark contrast between an initially upward trend in Scotland and in Northern Ireland, and continued severe decreases in England and in Wales. Pressures on migration and in the winter are likely to be affecting the population, as is a reduction in habitat quality on the breeding grounds ([Fuller \*et al.\* 2005](#)). The recent population decline is associated with a moderate decline in productivity as measured by CES and with a substantial increase in failure rates at the egg stage, which raises NRS concern ([Leech & Barimore 2008](#)). There has been no trend, however, in the number of fledglings per breeding attempt. Average laying dates have become a week earlier, perhaps in response to recent climatic warming ([Crick & Sparks 1999](#)). Numbers have fallen widely across Europe since 1980 ([PECBMS 2009](#)).

## GOLDCREST

### *Regulus regulus*

- Population changes
- Productivity trends
- Additional information

#### Conservation listings

Europe: no SPEC category (concentrated in Europe, conservation status favourable)

UK: green

#### Long-term trend

England: fluctuating, with no long-term trend

#### UK population size

842,000 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

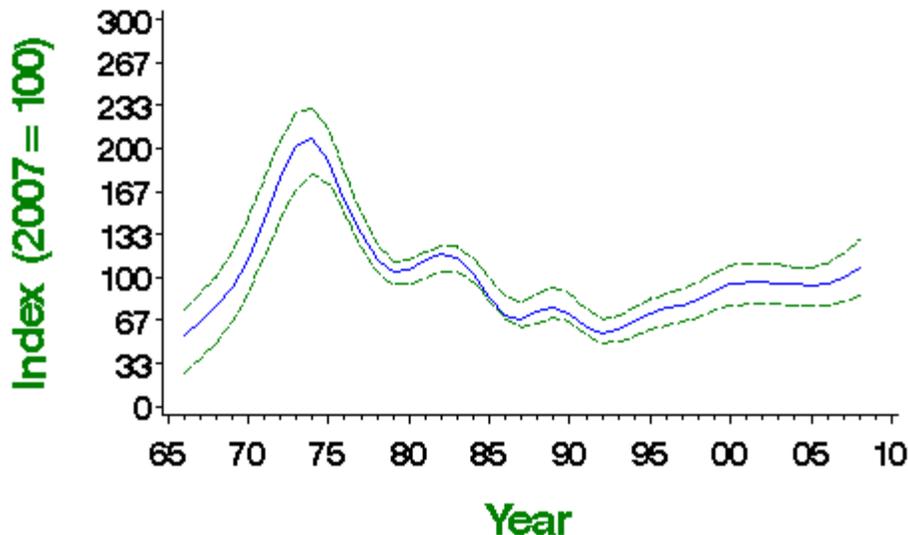

#### Status summary

Goldcrest abundance is unusually severely affected by winter weather, and the strong increase in the species' CBC/BBS index up to the mid 1970s can be interpreted as recovery from the cold winters of the early 1960s. The subsequent decline temporarily moved the species to the amber list, but its status has now been restored to green. Trends over longer and shorter periods all suggest population increase, and the long-term trend looks very much like a series of damped oscillations following the 1962/63 winter. The high amplitude of year-to-year change reflects the species high breeding potential, and its sensitivity to cold winter weather. BBS has recorded substantial increases in all UK countries except Wales, where a significant decline has been registered. CBC had relatively poor coverage of conifer plantations, in which Goldcrests occur at increasing densities as the trees mature. The increase in area of prime habitat has therefore been poorly reflected in the long-term trend. Numbers have fallen widely across Europe since 1980 ([PECBMS 2009](#)).

## SPOTTED FLYCATCHER

### *Muscicapa striata*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: SPEC category 3, declining

UK: red (>50% population decline)

UK Biodiversity Action Plan: [click here](#)

### Long-term trend

UK, England: rapid decline

### UK population size

63,700 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

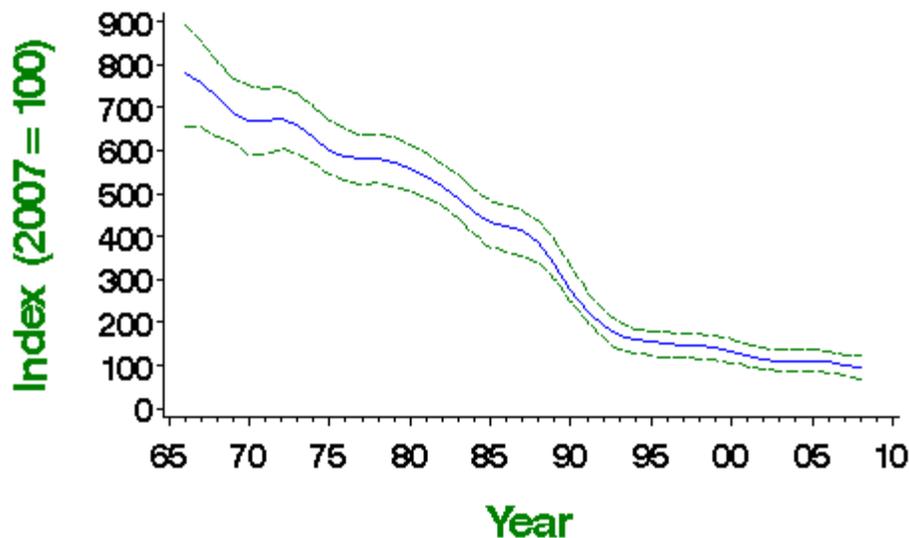

### Status summary

Spotted Flycatchers have declined rapidly and consistently since the 1960s according to census data, and the decline is also reflected in the trend revealed by CES. Productivity measures indicate lower clutch and brood sizes and greater nest losses at the egg and chick stages, which raise NRS concern ([Leech & Barimore 2008](#)), a drop in numbers of fledglings per breeding attempt, and a decrease overall in the ratio of juveniles to adults. Demographic modelling shows that decreases in the annual survival rates of birds in their first year of life are most likely to have driven the decline ([Freeman & Crick 2003](#)). Decreasing survival rates may have been caused by deteriorations in woodland quality, particularly leading to declines in the large flying insects that are food to the flycatcher, or by conditions either on the wintering grounds or along migration routes ([Fuller et al. 2005](#)). Since trends have been similar across UK regions and habitats, however, it is more likely that the decline has been driven by factors operating outside the UK. Spotted Flycatchers have declined widely across Europe since 1980 ([PECBMS 2009](#)). A predator 'control' experiment has indicated that the abundance of nest predators may be determining the breeding success of Spotted Flycatchers, especially in woodland, where nest success was lower overall than in gardens ([Stoate & Szczur 2006](#)). Another study using nest cameras has identified avian predators, especially [Jays](#), as responsible for most nest losses ([Stevens et al. 2008](#)).

## PIED FLYCATCHER

*Ficedula hypoleuca*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (concentrated in Europe, conservation status favourable)

UK: amber (25–50% decline)

### Long-term trend

UK: rapid decline

### UK population size

35,000–40,000 pairs in 1990 (1988–91 Atlas: [APEP06](#));

29,500–33,800 pairs in 2000 (updated using BBS trend: [BiE04](#))

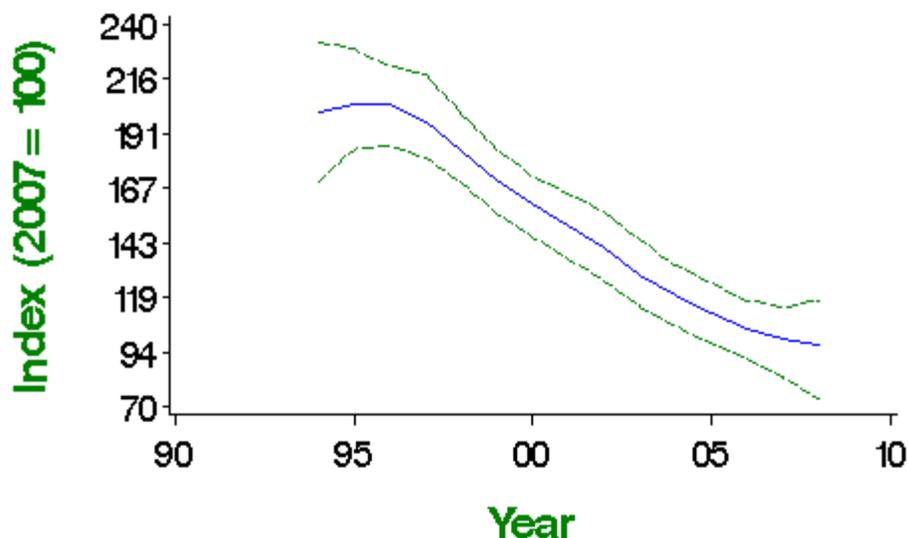

### Status summary

Pied Flycatchers are restricted to upland deciduous woods in parts of western and northern Britain. The proportions of CBC plots occupied rose during the 1980s, but the species was never numerous enough for trends to be estimated ([Marchant et al. 1990](#)). The 1988–91 breeding atlas revealed a small expansion in range since 1968–72, aided by the provision of nest boxes in new areas ([Gibbons et al. 1993](#)). BBS indicates that abundance has decreased steeply since 1994, prompting the species' recent move from the green to the amber list.

Percentage nestbox occupancy has also fallen over a similar period at a number of sites monitored as [RAS](#) projects. The reasons for this decline are unknown, but lie at least partly outside the breeding season ([Goodenough et al. 2009](#)). No trends are evident in the number of fledglings per breeding attempt. Numbers have fallen widely in Europe since 1980 ([PECBMS 2009](#)). In the Netherlands, climate change may have brought about decline in Pied Flycatchers by advancing the peak period of food availability for this species in deciduous forests – the birds being unable so far to compensate for the change in food supply by breeding earlier ([Both 2002](#), [Both et al. 2006](#)).

## LONG-TAILED TIT

*Aegithalos caudatus*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: green (species level); amber (race *rosaceus*, >20% of European breeders)

### Long-term trend

England: moderate increase

### UK population size

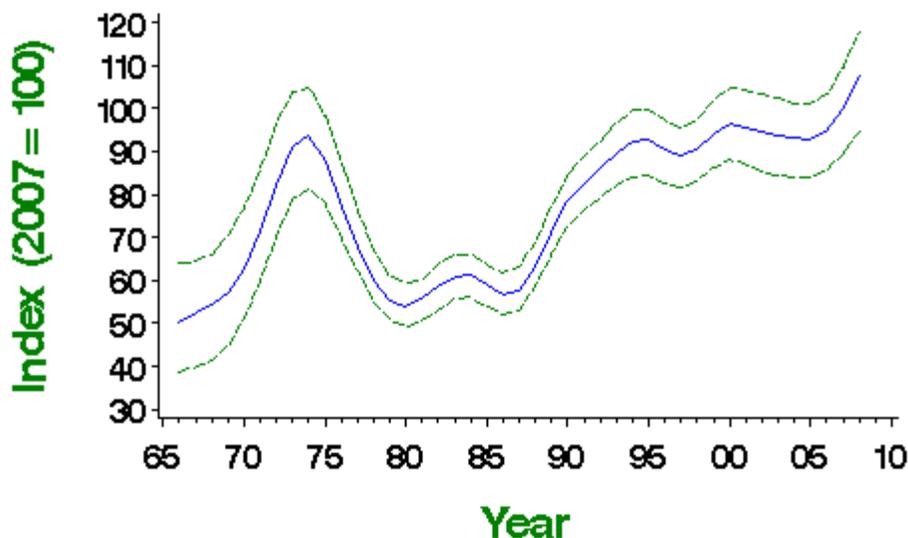

273,000 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

### Status summary

This species undergoes wide fluctuations in numbers between breeding seasons, suffering heavy mortality when winters are severe, but is able to recover quickly by virtue of its high breeding potential. Numbers were low after the severe winters of the early 1960s and again during a series of relatively cold winters beginning in the late 1970s. The starting years of the 25-year and longest monitoring periods coincided with troughs in population, thus exaggerating the long-term trend. CBC/BBS index trends show progressive increases in Long-tailed Tit abundance beginning in the early 1980s. Clutch and brood sizes have become smaller since the 1960s and, curiously, nest losses have switched from the egg to the chick stage. The overall effect of these changes has been a steep linear increase in the number of fledglings per breeding attempt. The marked trend towards earlier laying may be explained by recent climatic changes ([Crick & Sparks 1999](#)).

## BLUE TIT

*Cyanistes caeruleus*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (concentrated in Europe, conservation status favourable)

UK: green (species level); amber (race *obscurus*, >20% of European breeders)

### Long-term trend

UK, England: shallow increase

### UK population size

3,535,000 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

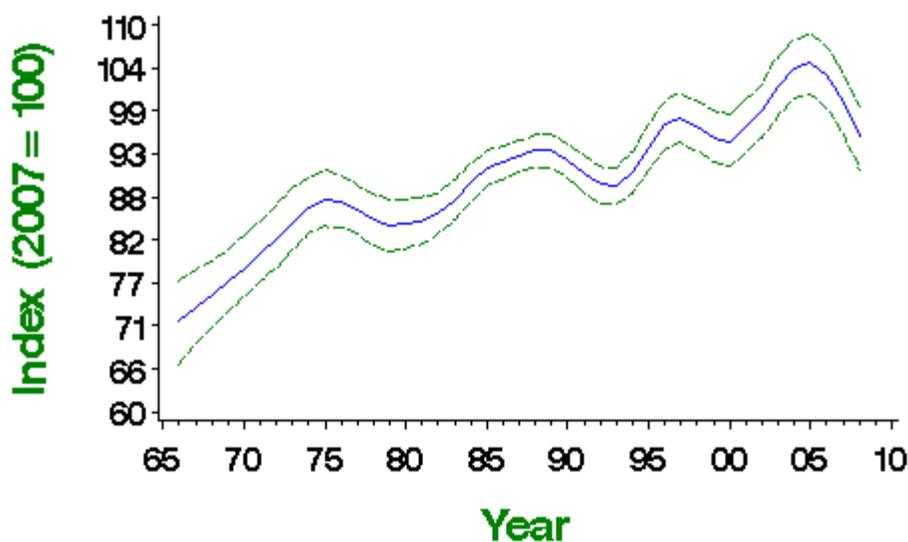

### Status summary

Blue Tit populations have increased in abundance, in parallel with those of [Great Tits](#), with brief pauses in the long-term upward trend. The recent years of the CBC/BBS index show fluctuations but the trend still appears to be upward. Food provision in gardens during winter and availability of nest boxes, which may reduce egg and nestling predation, have both increased and may have contributed to the rise in population. There have been no clear changes in fledglings per breeding attempt or in survival, however, to accompany the population increase. Numbers have risen widely in Europe since 1980 ([PECBMS 2009](#)).

## GREAT TIT

*Parus major*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: green (species level, race *major*); amber (race *newtoni*, >20% of European breeders)

### Long-term trend

UK, England: rapid increase

### UK population size

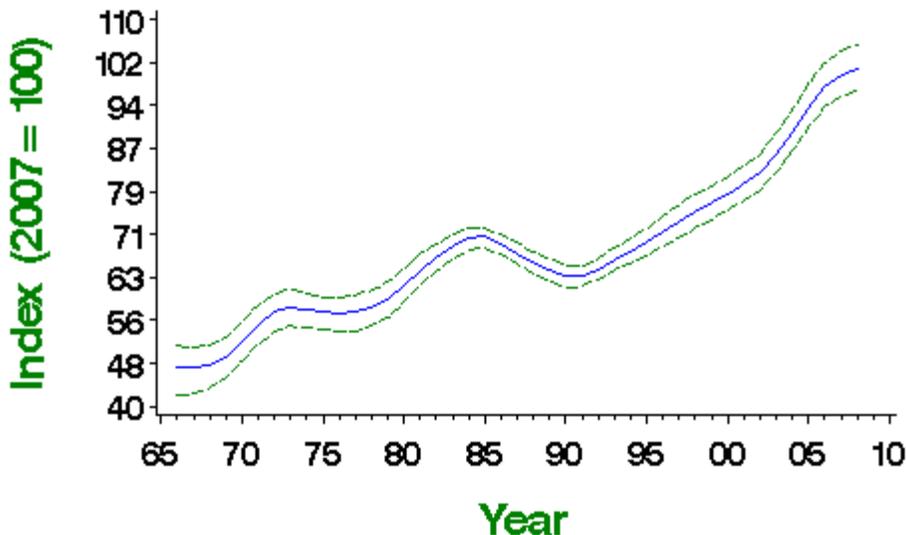

2,074,000 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

### Status summary

Great Tits have increased steadily since the 1960s, with the exception of two brief periods of stability or shallow decline during the mid 1970s and late 1980s. Recent CBC/BBS and BBS results suggest that this increase is continuing, in all UK countries. More widespread food provision in gardens during winter is one possible explanation for the increase. Changes in different aspects of breeding performance are contradictory: CES productivity has fluctuated, brood size has decreased, and nest success has improved at the egg stage but decreased at the chick stage. There has been no trend in the number of fledglings per breeding attempt. Laying date has advanced by about a week in the UK, in line with climatic change. In a Dutch study population, however, the breeding period did not advance during 1973–95 and became increasingly mistimed with respect to the peak of insect abundance ([Visser et al. 1998](#)).

## COAL TIT

### *Parus ater*

- Population changes
- Productivity trends
- Additional information

### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: green (species level, race *hibernicus*); amber (race *britannicus*, >20% of European breeders)

### Long-term trend

England: probable moderate increase

### UK population size

653,000 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

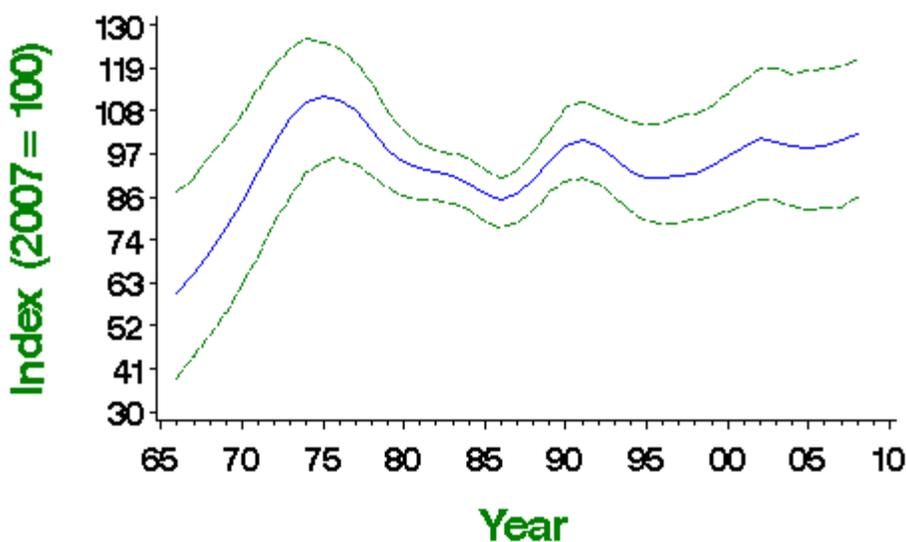

### Status summary

While other common tit species have increased, the UK Coal Tit population has been rather stable since the mid 1970s, following earlier rapid increase. The ratios of Coal Tit to [Blue](#) and [Great Tits](#) caught for ringing have both shown a sustained increase since 1960 ([Perrins 2003](#)), however, although in these figures population change may be confounded to some degree with changes in behaviour among birds and bird ringers. Confidence intervals are wide, but BBS shows large changes in population sizes that have varied geographically across the UK. This pattern suggests that Coal Tit abundance in the UK may be controlled by a complex range of factors.

## WILLOW TIT

*Poecile montana*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: red (>50% population decline)

UK Biodiversity Action Plan: priority species

### Long-term trend

UK, England: rapid decline

### UK population size

8,500 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

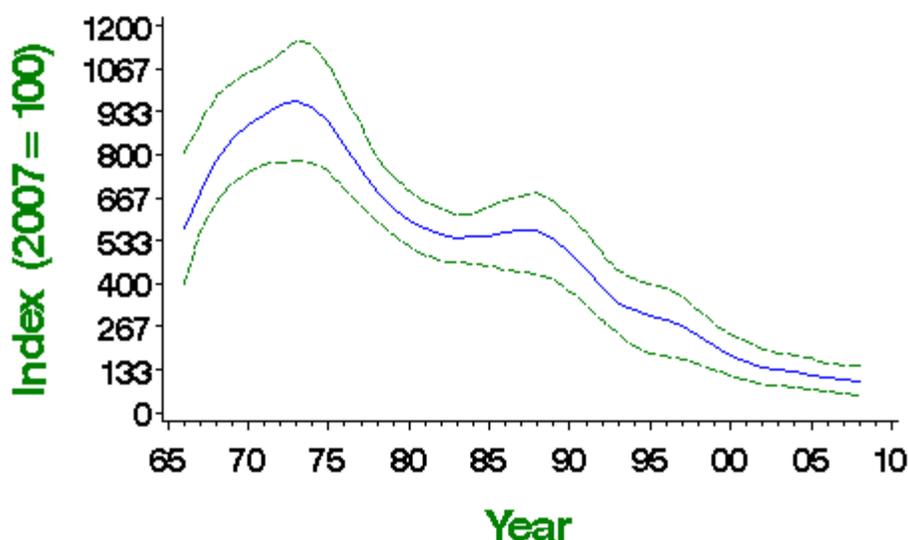

### Status summary

Willow Tits have been in decline since the mid 1970s, and have become locally extinct in an ever-growing number of former haunts. The continuing decline in the CBC/BBS index through the 1990s, following a brief period of stability during the 1980s, is replicated in the CES abundance trend. The UK conservation listing was upgraded from amber to red in 2002. Numbers have changed least in the wet woodlands that the species prefers ([Siriwardena 2004](#)). Farmland is now only rarely occupied. The most likely causes of decline are competition with other tit species, increasing nest predation by [Great Spotted Woodpeckers](#), and deterioration in the quality of woodland as feeding habitat for Willow Tits through canopy closure and increased browsing by deer ([Perrins 2003](#), [Siriwardena 2004](#), [Fuller et al. 2005](#)). A study of former CBC sites and other woods that were known to have held the species in the past found that the sites still holding Willow Tits tended to be wetter but did not differ in the density of potential nest predators or avian competitors ([Lewis et al. 2007](#), [2009](#)). Willow Tit is one of the most strongly declining bird species in Europe, having decreased at an annual rate of 4% during 1980–2006, but has declined to a lesser extent in central and east Europe than in the north, west and south ([PECBMS 2007](#), [2009](#)).

## MARSH TIT

### *Poecile palustris*

- Population changes
- Productivity trends
- Additional information

### Conservation listings

Europe: SPEC category 3, declining  
 UK: red (>50% population decline)  
 UK Biodiversity Action Plan: priority species

### Long-term trend

UK, England: rapid decline

### UK population size

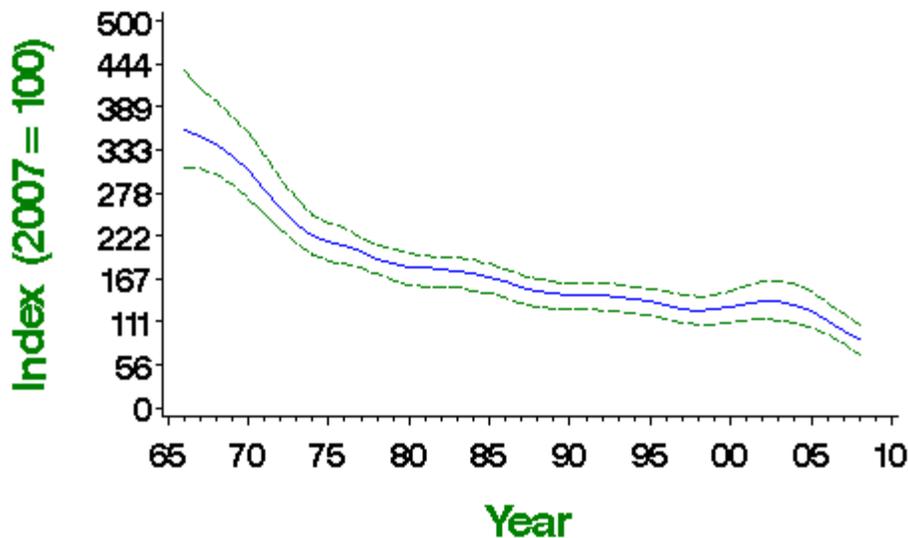

52,800 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP2](#))

### Status summary

Marsh Tit abundance has declined almost continuously since BTO monitoring began. The species' UK conservation listing has recently been upgraded from amber to red. Detailed demographic work suggests that the decline may have been driven by low annual survival, and that neither increased predation nor interspecific competition is responsible ([Siriwardena 2006](#)). Nest failure rates have fallen during the period of decline, but no trend is evident in the number of fledglings per breeding attempt. Marsh Tits nest in woods as small as half a hectare ([Hinsley et al. 1995](#)), but there is evidence from CBC that declines are steeper on smaller plots (G.M. Siriwardena, unpubl.). Reductions in the structural and floristic diversity of woodland, resulting partly from increased browsing by deer, are likely to have caused the decline ([Perrins 2003](#), [Fuller et al. 2005](#)). Marsh Tits appear to select breeding territories on the quality of the shrub layer rather than the tree canopy, and may be adversely affected by factors that damage the shrub layer, such as overgrazing and canopy closure ([Hinsley et al. 2007](#)). Numbers have fallen widely in Europe since 1980 ([PECBMS 2009](#)), and the European status of this species is no longer considered 'secure' ([BirdLife International 2004](#)).

## NUTHATCH

*Sitta europaea*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: green

### Long-term trend

UK, England: rapid increase

### UK population size

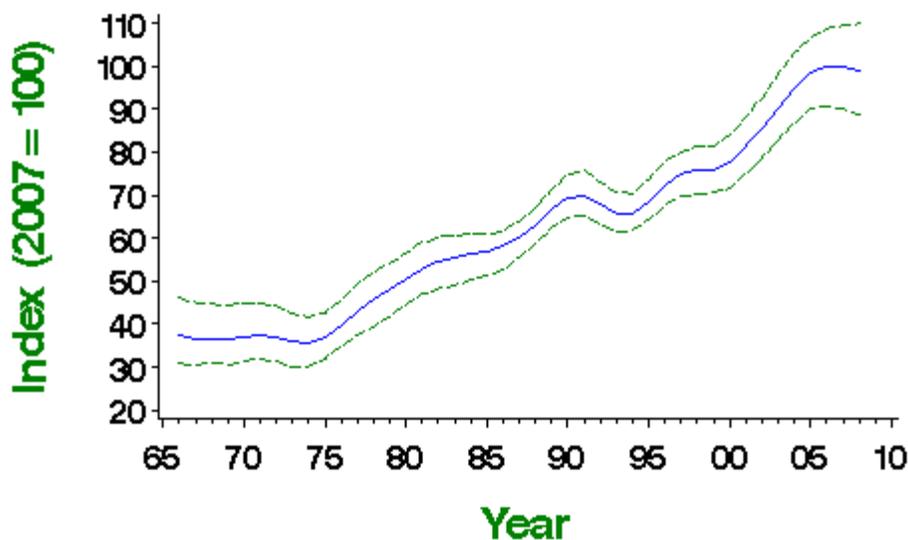

144,000 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

### Status summary

Nuthatch abundance has increased rapidly since the mid 1970s. Despite minor setbacks during the 1990s, there is no indication yet of a halt to the upward trend. This increase has been accompanied by a range expansion into northern England ([Gibbons et al. 1993](#)) and southern Scotland, and has been associated with a large increase in brood size, reduced nest failure, and linear increase in the number of fledglings per breeding attempt. The reasons for these changes are unknown. A trend towards earlier laying, perhaps as a result of climate change ([Crick et al. 1997](#)), has also been identified. Numbers have risen widely in Europe since 1980 ([PECBMS 2009](#)).

## TREECREEPER

### *Certhia familiaris*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: green (species level); amber (race *britannica*, >20% of European breeders)

### Long-term trend

UK, England: fluctuating, with no long-term trend

### UK population size

214,000 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

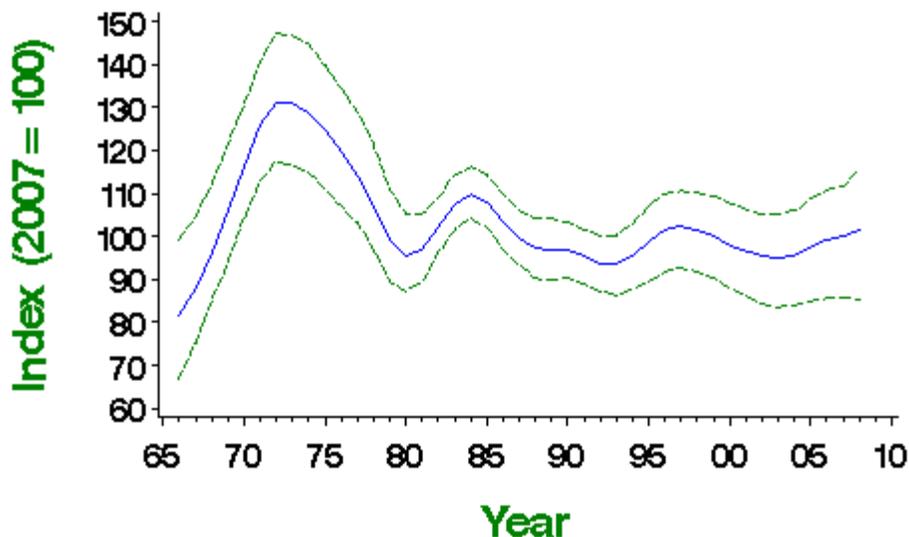

### Status summary

The UK Treecreeper population peaked in the mid 1970s, but has been roughly stable since about 1980. Intensive study has shown that Treecreeper numbers and survival rates are reduced by wet winter weather ([Peach et al. 1995b](#)). The influence of cold weather is also evident in the low start to the index, following the severe winter of 1962/63, and the trough around 1980. Census data suggest a minor decline has occurred since the early 1980s, but CES adult captures have increased for much of this period. Productivity, calculated using CES data, shows fluctuations around a long-term shallow increase but a sharp downturn in recent years. There has been a significant fall in nest failure rates at the egg stage (18 days, comprising 14 days incubation and 4 days laying). The trend towards earlier laying can be partly explained by recent climate change ([Crick & Sparks 1999](#)).

## JAY

### *Garrulus glandarius*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)  
 UK: green (species level); amber (races *hibernicus* and *rufitergum*, >20% of European breeders)

### Long-term trend

UK, England: fluctuating, with no long-term trend

### UK population size

160,000 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

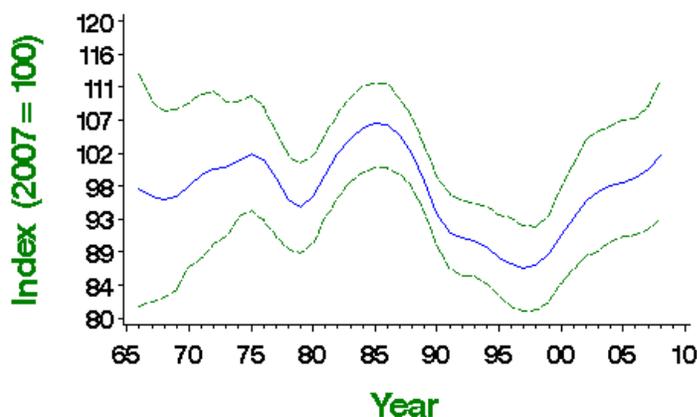

### Status summary

The UK Jay population remained stable in the species' preferred woodland habitat until the late 1980s, after which the population began to decline. This decrease followed an earlier decline on farmland CBC plots ([Gregory & Marchant 1996](#)). Long-term trends are stable overall, and the CBC/BBS index has recorded some increase in the recent ten-year period. No trends are known in breeding performance.

## JACKDAW

*Corvus monedula*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (concentrated in Europe, conservation status favourable)

UK: green

### Long-term trend

UK, England: moderate increase

### UK population size

555,000 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

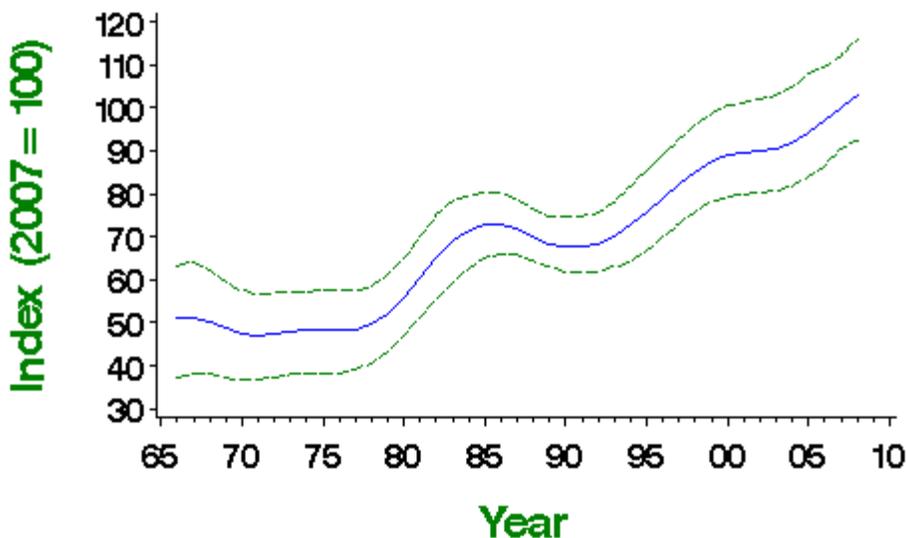

### Status summary

Jackdaws have increased in abundance since the 1960s ([Gregory & Marchant 1996](#)), and more recent BBS data suggest that the increase is continuing in all UK countries. As with [Magpie](#), [Rook](#) and [Carrion Crow](#), the increase has been associated with improvements in breeding performance and probably reflects the species' generalist feeding habits, which allow it to exploit diverse and ephemeral food resources. A minor decrease in average brood size has been countered by substantial declines in nest failure rates during the egg and chick stages, and the number of fledglings per breeding attempt has improved steadily. Typically in this species, the younger chicks of a brood perish quickly if food becomes limited. Increases in fledging success are therefore likely to be due to improved provisioning by the parents ([Henderson & Hart 1993](#)).

## ROOK

*Corvus frugilegus*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: green

### Long-term trend

UK: increase

### UK population size

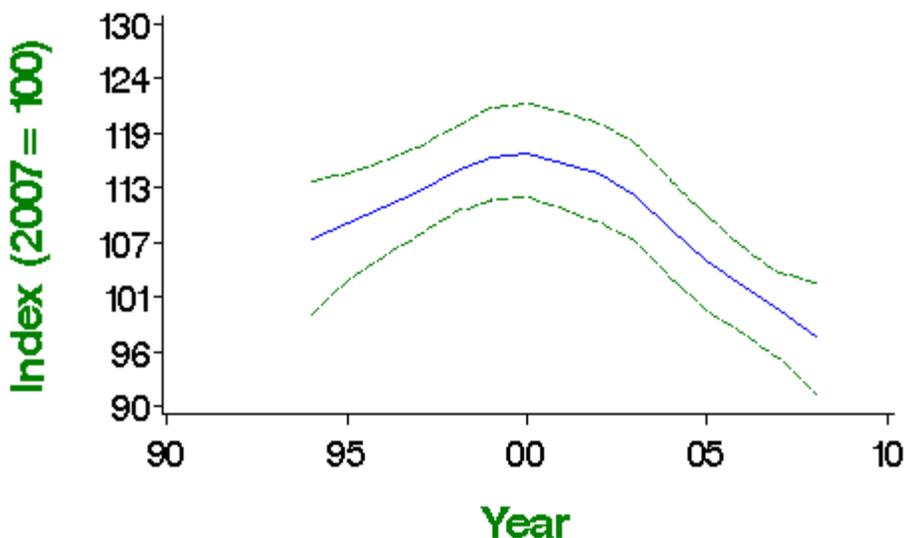

1,120,000–1,430,000 pairs in 1996 (Marchant & Gregory 1999: BiE04); 1,130,000–1,440,000 pairs in 2000 (1996 estimate updated using BBS trend: APEP06)

### Status summary

Relatively few rookeries fell within CBC plots, but an index calculated from the available nest counts showed a shallow, long-term increase (Wilson *et al.* 1998). The trend is confirmed by the results of the most recent BTO rookeries survey, which identified a 40% increase in abundance between 1975 and 1996 (Marchant & Gregory 1999). This increase probably reflects the species' considerable adaptability in the face of agricultural change. BBS indices, which are drawn from sightings during transect walks and not from the BBS's nest counts, suggest that some decrease has occurred subsequently, especially in Scotland and Northern Ireland since around 2000. There has been little change in breeding productivity since the 1960s but a minor decrease in brood size is now becoming evident.

## CARRION CROW

*Corvus corone*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe (*C. corone/cornix*): no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK (*C. corone/cornix*): green

### Long-term trend

England: rapid increase

### UK population size

790,000 territories in 1990 (1988–91 Atlas: [APEP06](#)); 987,500 pairs in 2000 (updated using CBC/BBS trend)

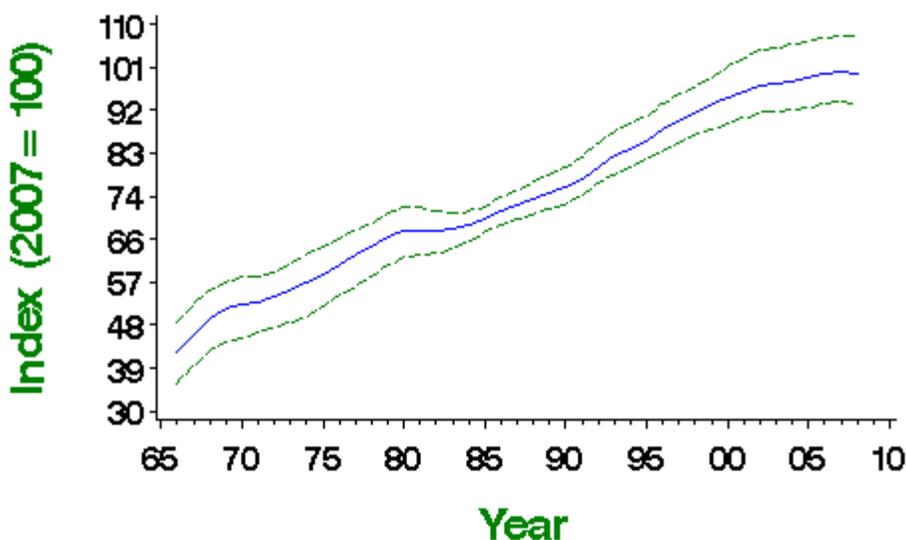

### Status summary

Carrion Crows have increased steadily since the 1960s ([Gregory & Marchant 1996](#)) and only now are there any signs of the UK population size stabilising. This trend has been associated with increases in nesting success and with earlier laying (perhaps an effect of climate change: [Crick et al. 1997](#)) and probably reflects the species' adaptability to changing habitats and the exploitation of ephemeral food resources in intensive agriculture. Unlike that of [Magpie](#), the increase was unaffected by the introduction of Larsen traps around 1990. Also unlike [Magpie](#), Carrion Crows have shown no levelling off of the long-term increase in fledglings per breeding attempt. [Bag returns](#) show little change in the numbers of crows killed by gamekeepers since 1960, suggesting that control on shooting estates may be stabilising numbers there and that the increases are occurring on unkept farmland and in other habitats.

## HOODED CROW

*Corvus cornix*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe (*C. corone/cornix*): no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: green

### Long-term trend

UK: uncertain

### UK population size

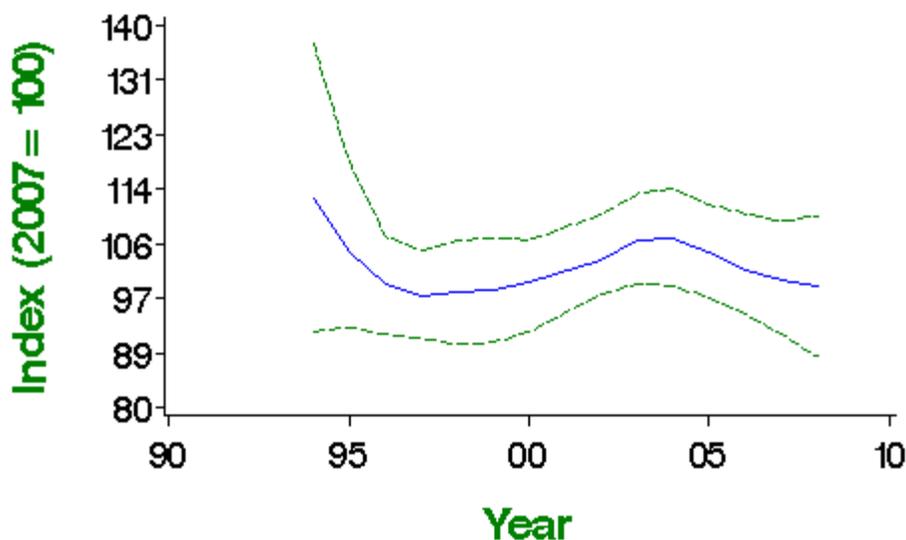

213,900 territories in 1990 (1988–91 Atlas: [APEP06](#))

### Status summary

The BOU Records Committee took the decision in 2002 to treat Hooded Crow and [Carrion Crow](#) as separate species ([Parkin et al. 2003](#)). This split is not yet recognised in European conservation listings. In the UK, Hooded Crows occur in Northern Ireland, the Isle of Man, and in Scotland, mainly west and north of the Great Glen. Retrospective analysis of BBS trends is simple because observers record Hooded Crows (coded HC) separately from Carrion Crows and from intermediates (coded HB). Intermediate forms between Carrion and Hooded, which predominate in a band across western Scotland and occur less frequently elsewhere in the UK, are not included in either BBS index. BBS data suggest that some decrease in Hooded Crows may have occurred in Scotland, but that this has been countered by increase in Northern Ireland. Hooded Crows have increased markedly in Ireland since 1924 ([Hutchinson 1989](#)).

## STARLING

### *Sturnus vulgaris*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: SPEC category 3 (declining)

UK: red (species level, race *vulgaris*); amber (race *zetlandicus*, >20% of European breeders)

UK Biodiversity Action Plan: priority species

### Long-term trend

England: rapid decline

### UK population size

804,000 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#));

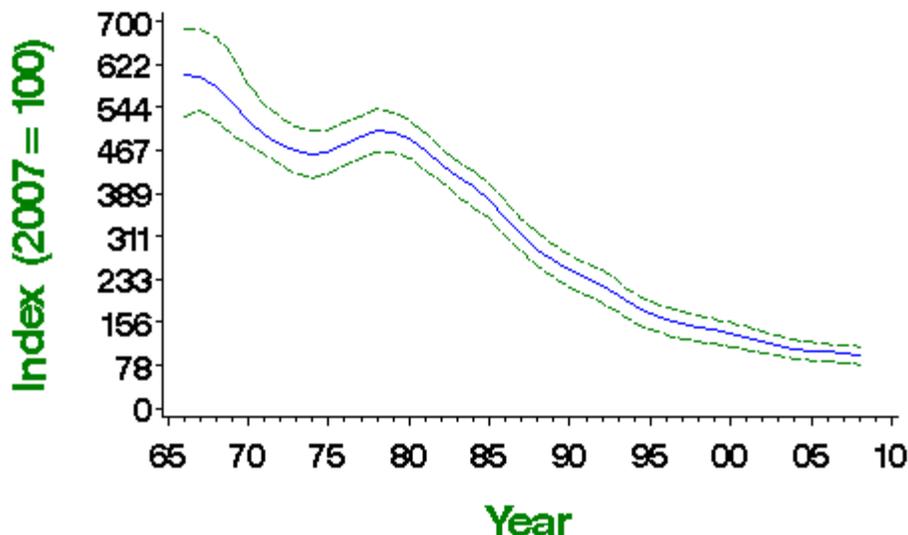

8,500,000 birds in Britain in 1994–2000 ([Robinson et al. 2005a](#))

### Status summary

The abundance of breeding Starlings in the UK has fallen rapidly, particularly since the early 1980s, and especially in woodland ([Robinson et al. 2002](#), [2005a](#)) and continues to be strongly downward. The declines have been greatest in the south and west of Britain; recent BBS data suggest that populations are also decreasing in Scotland and Northern Ireland, where the trends were initially upward. The species' UK conservation listing has been upgraded from amber to red as the decline has become more severe. Strong improvements have occurred in breeding performance, suggesting that decreasing survival rates, particularly of young birds, may be responsible for the observed decline ([Freeman et al. 2002](#), [2007b](#)). Loss of permanent pasture, which is the species' preferred feeding habitat, and general intensification of livestock rearing are likely to be having adverse effects on rural populations, but other causes should be sought in urban areas ([Robinson et al. 2002](#), [2005a](#)). As the population has dropped, the numbers of fledglings per breeding attempt has increased markedly; clutches are now larger, and rates of nest loss have fallen. Widespread declines in northern Europe during the 1990s outweighed increases in the south, and the European status of this species is no longer considered 'secure' ([BirdLife International 2004](#)).

## HOUSE SPARROW

*Passer domesticus*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: SPEC category 3, declining

UK: red (>50% population decline)

UK Biodiversity Action Plan: priority species

### Long-term trend

England: rapid decline

### UK population size

2,100,000–3,675,000 pairs in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#)); about 6 million pairs in Britain ([Robinson et al. 2005b](#))

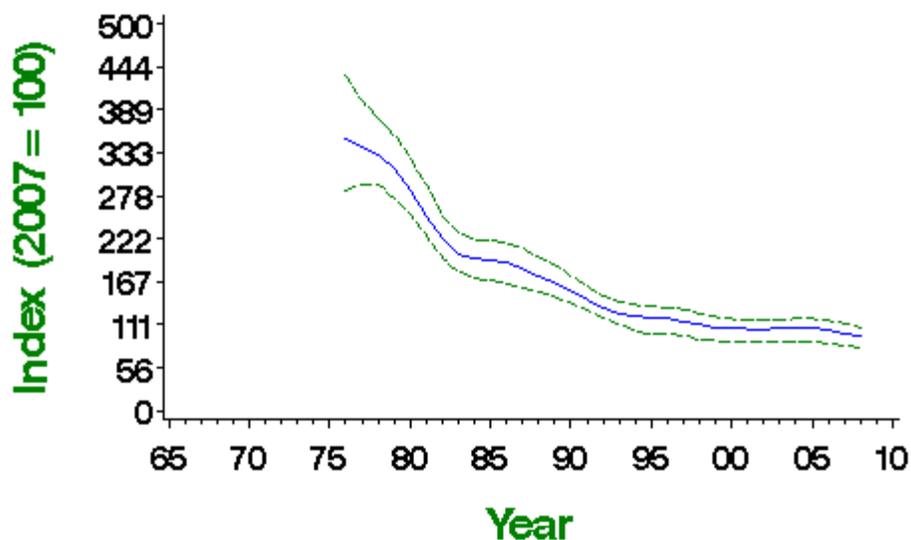

### Status summary

CBC sample sizes did not allow monitoring of House Sparrows until 1976; previously, there had been many farmland plots with high populations that could not be properly quantified without better access to farm buildings and housing. CBC/BBS data indicate a rapid decline in abundance over the last 25 years, as does the BTO's Garden Bird Feeding Survey ([Siriwardena et al. 2002](#), [Robinson et al. 2005b](#)). These results are supported by many other studies and anecdotal reports, and have generated great conservation concern (see [Summers-Smith 2003](#)). A change in the listing criteria resulted in the admission of the species, green-listed until 2002, to the red list. A temporary drop in first-year survival coincided with the steepest decline, but changes in breeding performance, especially nest failure rates at the chick stage, have also helped drive population change ([Freeman & Crick 2002](#)). Possible explanations include a general reduction in food supply, less grain being spilt during agricultural operations, tighter hygiene regulations, increases in predation, and toxic additives to unleaded petrol ([Siriwardena et al. 2002](#), [Robinson et al. 2005b](#), [Vincent 2005](#), [Summers-Smith 2007](#), [Peach et al. 2008](#)).

The overall national decline since the 1970s masks much heterogeneity by region and habitat, and population processes may be relatively fine-grained: overall, populations in rural areas had declined by 47% by 2000, and those in urban and suburban areas by about 60% (CBC data: [Robinson et al. 2005b](#)). Within urban areas, House Sparrows may have disappeared predominantly from more affluent areas, where changes are more likely to have occurred to habitat structure ([Shaw et al. 2008](#)). The continued availability of allotments, gardens and other green spaces in urban areas is crucial to preventing further decline ([Chamberlain et al. 2007](#)). BBS suggests increases recently in Wales, Northern Ireland and Scotland. Overall, brood size has decreased, raising NRS concern ([Leech & Barimore 2008](#)), but the number of fledglings per breeding attempt has improved markedly. The European status of this species is no longer considered 'secure' ([BirdLife International 2004](#)), following widespread declines across Europe since 1980 ([PECBMS 2009](#)).

## CHAFFINCH

*Fringilla coelebs*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (concentrated in Europe, conservation status favourable)

UK: green (species level); amber (race *gengleri*, >20% of European breeders)

### Long-term trend

UK, England: shallow increase

### UK population size

5,974,000 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

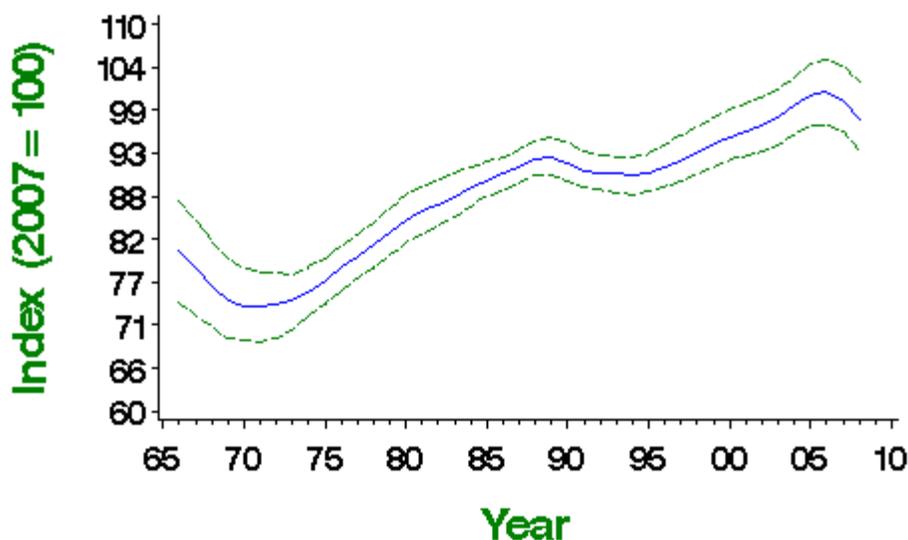

### Status summary

Chaffinch abundance has increased rapidly since the early 1970s, according to CBC/BBS and CES, but numbers seemed to stabilise for a period during the 1990s. This relative stability was associated with a reduction in annual survival, which could be density-dependent ([Siriwardena et al. 1999](#)). There was also some evidence of improved breeding performance during the early years of population increase, with larger brood sizes, fewer egg-stage nest failures, and more fledglings per breeding attempt, but these trends are now reversed. The trend towards earlier laying may be partly explained by recent climate change ([Crick & Sparks 1999](#)). Chaffinches are well adapted to suburban and garden habitats, as well as to highly fragmented woodland and hedgerows, occurring less in the open-field, arable habitats that have been affected most by agricultural intensification, so it is possible that they have benefited by environmental changes from which other seed-eating passerines have suffered.

## GREENFINCH

### *Carduelis chloris*

• Population changes

• Productivity trends

• Additional information

#### Conservation listings

Europe: no SPEC category (concentrated in Europe, conservation status favourable)

UK: green (species level, race *chloris*); amber (race *harrisoni*, >20% of European breeders)

#### Long-term trend

UK, England: shallow increase

#### UK population size

734,000 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

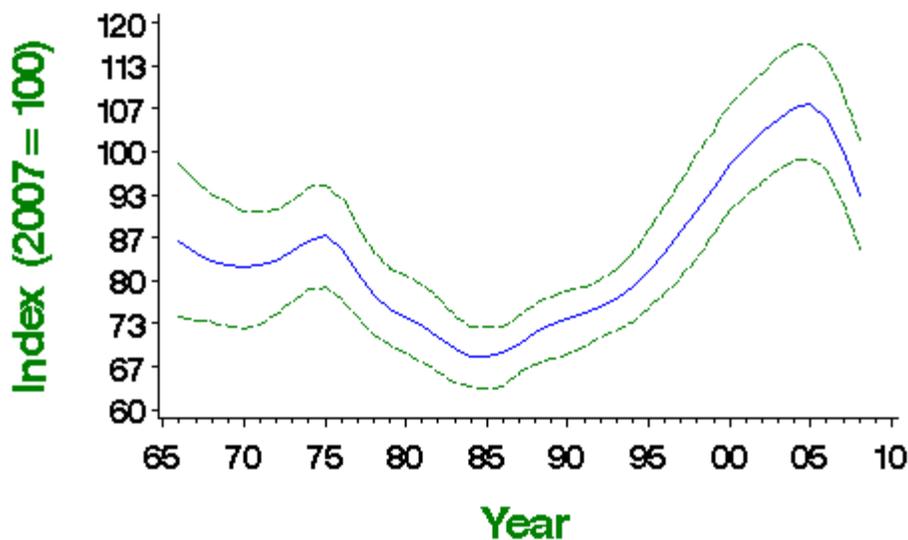

#### Status summary

Greenfinch abundance varied little up to the mid 1990s, and there was little change in either survival or breeding performance during this period ([Siriwardena et al. 1998b](#), [2000b](#)). More recent CBC/BBS data indicate population increases widely across the UK. Productivity data have become more complex, with a substantial reduction in brood size and increased nest survival at the egg stage. Possibly these recent changes are linked to the species' regular year-round use of gardens for feeding. Overall, however, there has been no change in the number of fledglings per breeding attempt. The trend towards earlier laying may be explained by recent climate change ([Crick & Sparks 1999](#)).

## GOLDFINCH

### *Carduelis carduelis*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: green (species level); amber (race *britannica*, >20% of European breeders)

### Long-term trend

England: shallow increase

### UK population size

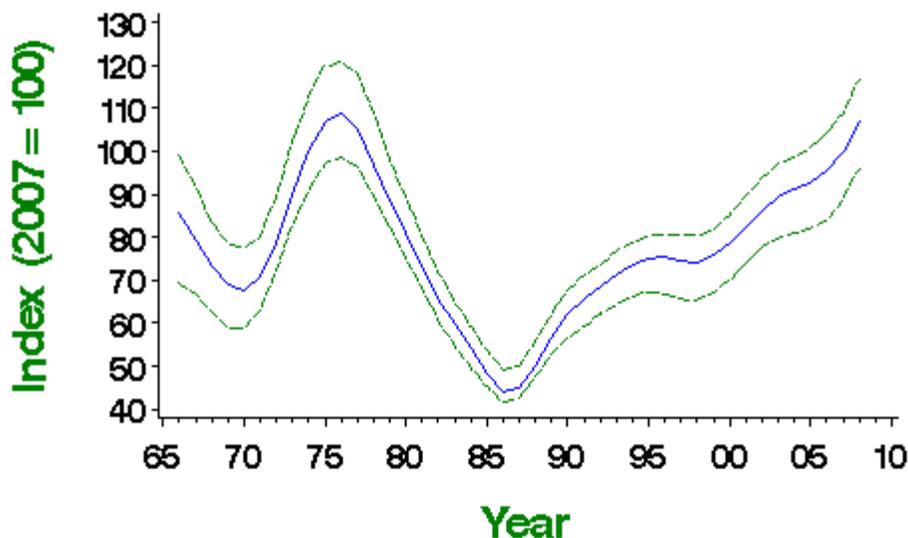

313,000 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

### Status summary

Goldfinch abundance fell sharply from the mid 1970s until the mid 1980s, but the decline was both preceded and followed by significant population increases. The recent upturn has lifted the species from the amber list of conservation concern into the green category, and has been accompanied by an increase in its use of gardens for winter feeding. These population changes can be explained almost entirely by changes in annual survival rates, which may have resulted from a reduction in the availability of weed seeds, due to agricultural intensification, and subsequent increased use of other food sources such as garden bird tables. Alternatively, the effects of environmental change or increased hunting pressure in France and Iberia, where the migrant majority of the population wintered, may have temporarily reduced survival rates ([Siriwardena et al. 1999](#)). There has been some long-term reduction in productivity as measured by CES, but no change in the number of fledglings per breeding attempt.

## SISKIN

### *Carduelis spinus*

• Population changes

• Productivity trends

• Additional information

#### Conservation listings

Europe: no SPEC category (concentrated in Europe, conservation status favourable)

UK: green

#### Long-term trend

UK: increase

#### UK population size

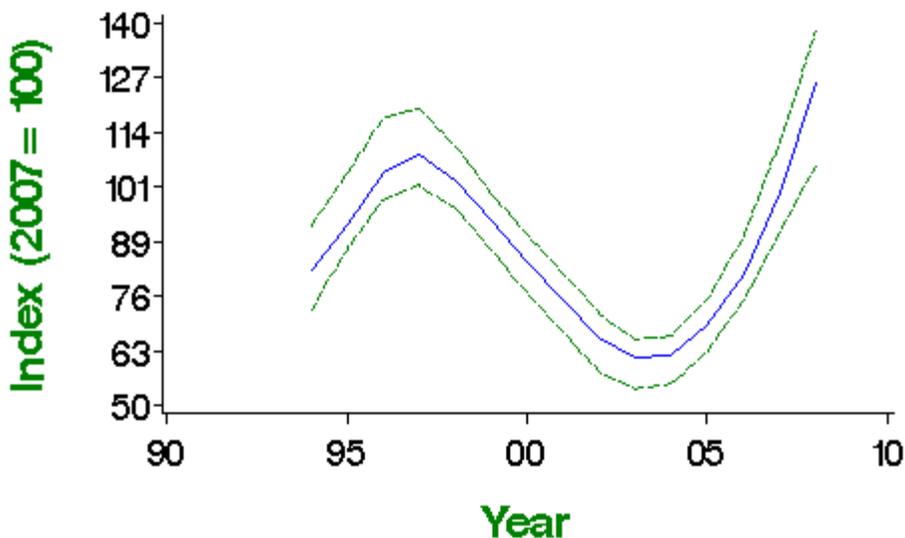

369,000 pairs in 2000 (1988–91 Atlas estimate updated using BBS trend: [BiE04](#), [APEP06](#))

#### Status summary

The maturing of new conifer plantations has aided the spread of breeding Siskins throughout the UK, from their previous stronghold in the Scottish Highlands, since about 1950. Its habit of using garden feeders, especially in late winter, has developed since the 1960s and, despite many of the birds involved migrating to the Baltic region to breed, may also have helped to boost the UK breeding population. The 1988–91 Breeding Atlas identified a considerable expansion of the breeding range into southern Britain ([Gibbons \*et al.\* 1993](#)). More CBC plots became occupied during the 1970s and 1980s, but samples were still insufficient for annual monitoring until BBS began in 1994. Results since then show extraordinary fluctuations, in both England and Scotland, which have been largely in parallel. To some extent, this may reflect the occasional large continental influxes affecting numbers on a broad UK scale.

## LINNET

### *Carduelis cannabina*

• Population changes

• Productivity trends

• Additional information

#### Conservation listings

Europe: SPEC category 2, declining

UK: red (species level, race *cannabina*); amber (race *autochthona*, >20% of European breeders, European status)

UK Biodiversity Action Plan: [click here](#)

#### Long-term trend

England: rapid decline

#### UK population size

556,000 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

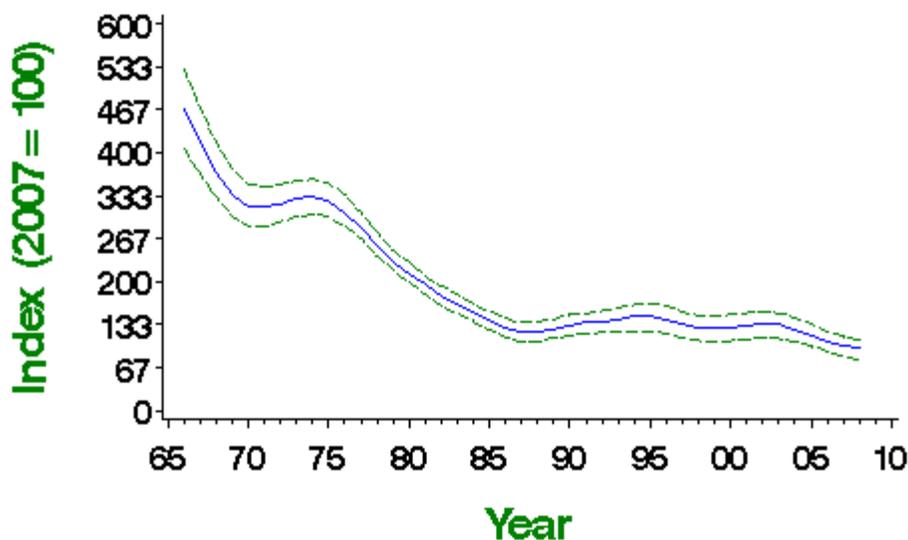

#### Status summary

Linnet abundance fell rapidly in the UK between the mid 1970s and mid 1980s. Numbers have subsequently changed little overall, although with further decrease in England and Wales and possibly some increase in Northern Ireland. CES has shown declines continuing strongly in recent years. Nest failure rates rose during the principal period of population decline, and this represents the most likely demographic mechanism driving the observed decreases in abundance ([Siriwardena et al. 1999, 2000b](#)). Low productivity is an ongoing problem for the species, possibly due to reductions in hedgerow quality leaving nests more exposed and therefore at greater risk of predation. Recent decreases in clutch and brood sizes, and in nest survival at the chick stage, raise NRS concern ([Leech & Barimore 2008](#)), and the number of fledglings per breeding attempt shows a linear decrease. Nestling diet incorporates a high proportion of oilseed rape seeds, suggesting that the inclusion of this crop in arable rotations may be important in maintaining Linnet populations ([Moorcroft et al. 2006](#)). A rapid decline is evident widely across Europe since 1980 ([PECBMS 2009](#)), and the European status of this species is no longer considered 'secure' ([BirdLife International 2004](#)).

## LESSER REDPOLL

### *Carduelis cabaret*

- Population changes
- Productivity trends
- Additional information

### Conservation listings

Europe (*C. cabaret/flammea*): no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: red

UK Biodiversity Action Plan: priority species

### Long-term trend

England: rapid decline

### UK population size

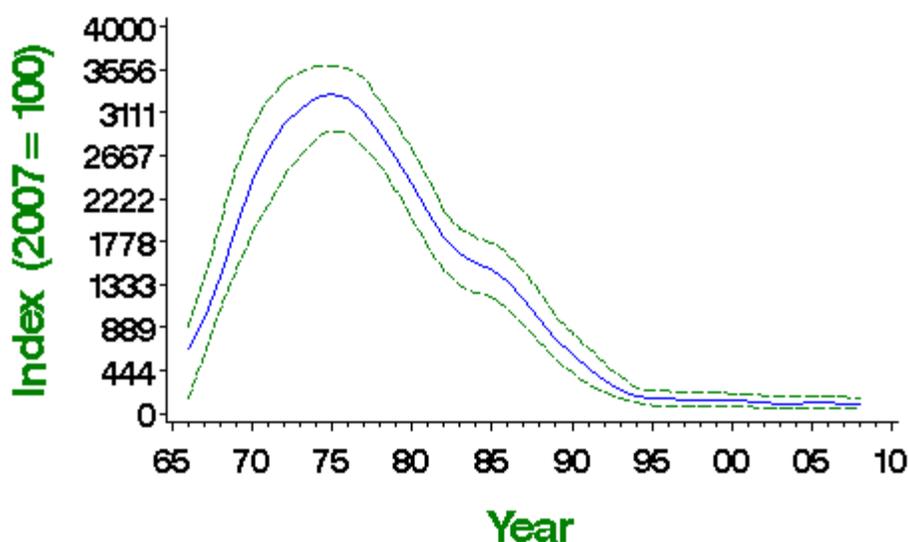

26,900 pairs in 2000 (1988–91 Atlas estimate updated using CBC trend: [BiE04](#), [APEP06](#))

### Status summary

Lesser Redpolls were abundant and widespread on CBC and CES plots in lowland Britain in the 1970s, but are largely absent now as breeding birds after a sustained period of severe decline. Uncertainty about the representativeness of the monitoring data prior to the establishment of BBS had denied the species a place on the red list, since it was thought possible that the population may have withdrawn from the lowlands to northern and western UK regions, where monitoring prior to 1994 was less effective. No evidence for such a shift exists, however: the species was moved from green to amber in 2002 and now to red. The 1988–91 Atlas showed a range contraction of 11% since 1968–72, which is evident in all parts of the UK ([Gibbons et al. 1993](#)). In southern Britain, at least, decrease may be attributable to a reduction in the amount of suitable young forest growth ([Fuller et al. 2005](#)). CES data indicate a rapid long-term decline in productivity, and there is evidence that survival rates have also fallen ([Siriwardena et al. 1998a](#)). Since *C. cabaret* is now widely treated as a separate species from the Common Redpoll *C. flammea*, and has a restricted range that lies wholly within western Europe, it is likely to gain a European conservation listing at the next review.

## BULLFINCH

*Pyrrhula pyrrhula*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: amber (25–50% population decline)

UK Biodiversity Action Plan: [click here](#)

### Long-term trend

UK: moderate decline

England: rapid decline

### UK population size

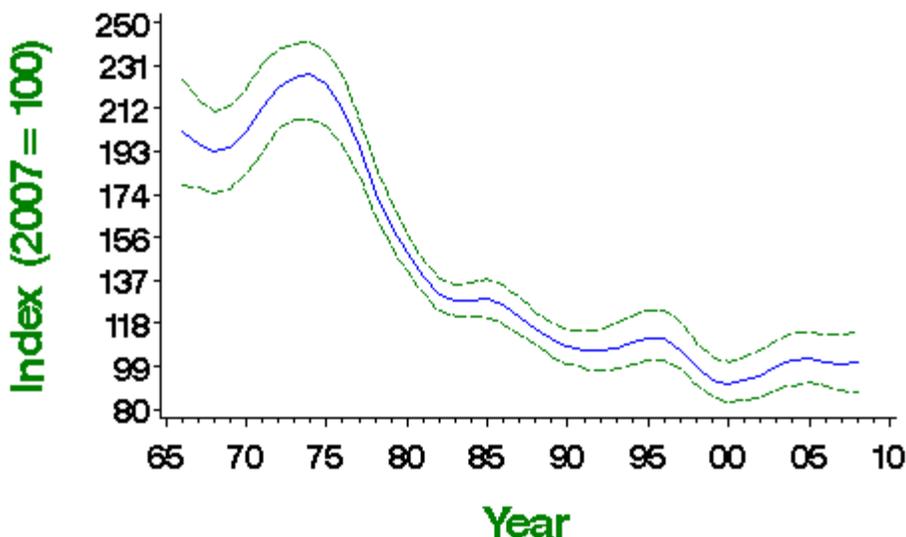

166,000 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

### Status summary

The UK Bullfinch population entered a long period of decline in the mid 1970s, following a period of relative stability. The decline was initially very steep, and more so in farmland than in wooded habitats, but has been shallower since the early 1980s. CES and CBC/BBS both suggest there are large fluctuations around the overall downward trend. The demographic mechanism of decline remains unclear ([Siriwardena et al. 1999, 2000b, 2001](#)), although agricultural intensification and a reduction in the structural and floristic diversity of woodland are suspected to have played a part through losses of food resources and nesting cover ([Fuller et al. 2005](#)). Alongside these factors, [Proffitt et al. \(2004\)](#) and [Marquiss \(2007\)](#) mention the constraints on survival outside the breeding season and the possible role of increasing Sparrowhawk populations on the ability of Bullfinches to exploit resources in some habitats. Recent decreases in brood size and in nest survival have raised NRS concern ([Leech & Barimore 2008](#)), and the trend in fledglings per breeding attempt is downward. Numbers have fallen widely in Europe since 1980 ([PECBMS 2009](#)). The UK conservation listing was downgraded from red to amber in 2009, but the scale of decline still places the species near the borderline between these categories.

**UK population size**

792,000 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

**Status summary**

Yellowhammer abundance began to decline on farmland in the mid 1980s and, except in Scotland, the decline has continued ever since. The species, listed as green in 1996, has been red listed since 2002. While there is some evidence that survival rates have decreased during the period of decline, Yellowhammer breeding performance has tended to improve ([Siriwardena \*et al.\* 1998b, 2000b](#)). However, recent declines in clutch size, brood size and nest success are of NRS concern ([Leech & Barimore 2008](#)). The number of fledglings per breeding attempt rose until about 1990 but is now in decline. Overall nest failure rates are relatively high, probably because later nests, which tend to be more successful ([Kyrkos 1997](#)), are under-represented in the NRS data set, but this is unlikely to affect overall trends. Reductions in winter seed food availability as a result of agricultural intensification (for example, the loss of winter stubbles and a reduction in weed densities) are widely believed to have contributed to the population decline. [Gillings \*et al.\* \(2005\)](#) have identified better population performance in areas with extensive winter stubble, presumably because overwinter survival is relatively high. The local availability of winter setaside is a good predictor of sites chosen for breeding territories the next year ([Whittingham \*et al.\* 2005](#)). Numbers have fallen widely in Europe since 1980 ([PECBMS 2009](#)).

## REED BUNTING

*Emberiza schoeniclus*

• Population changes

• Productivity trends

• Additional information

### Conservation listings

Europe: no SPEC category (favourable conservation status in Europe, not concentrated in Europe)

UK: amber (25–50% population decline to 2006)

UK Biodiversity Action Plan: [click here](#)

### Long-term trend

UK, England: shallow decline

### UK population size

192,000–211,000 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS and WBS trends:

[BiE04](#), [APEP06](#))

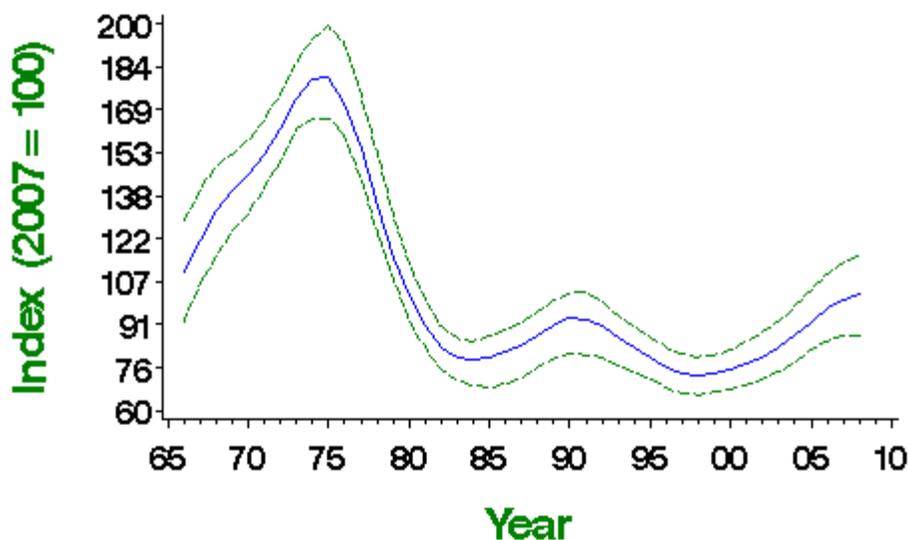

### Status summary

Both CBC/BBS and WBS/WBBS indices declined rapidly during the 1970s, but Reed Bunting abundance subsequently remained remarkably stable. In recent years, results from BBS indicate significant population increase. The early increase in the CBC index was associated with a gradual spread into drier habitats, especially farmland, and it is likely that the subsequent decline was related to agricultural intensification. Detailed demographic analyses suggest that the decline was driven by decreasing survival rates and that a subsequent population recovery may have been prevented by increased nest losses ([Peach et al. 1999](#)). This is supported by a moderate decline in CES productivity and by a major increase in failure rates at the egg stage, which has raised NRS concern ([Leech & Barimore 2008](#)). There has been linear decline in numbers of fledglings per breeding attempt. Farmland densities are four times higher in oilseed rape than in cereals or setaside and this crop is crucial in reducing the dependency of the species on wetlands ([Gruar et al. 2006](#)). The initial decline placed Reed Bunting on the red list but in 2009, with evidence from waterways and from BBS of some recovery in numbers, the species was moved from red to amber.

**CORN BUNTING***Emberiza calandra*

• Population changes

• Productivity trends

• Additional information

**Conservation listings**

Europe: SPEC category 2 (declining)

UK: red (&gt;50% population decline, historical decline)

UK Biodiversity Action Plan: [click here](#)**Long-term trend**

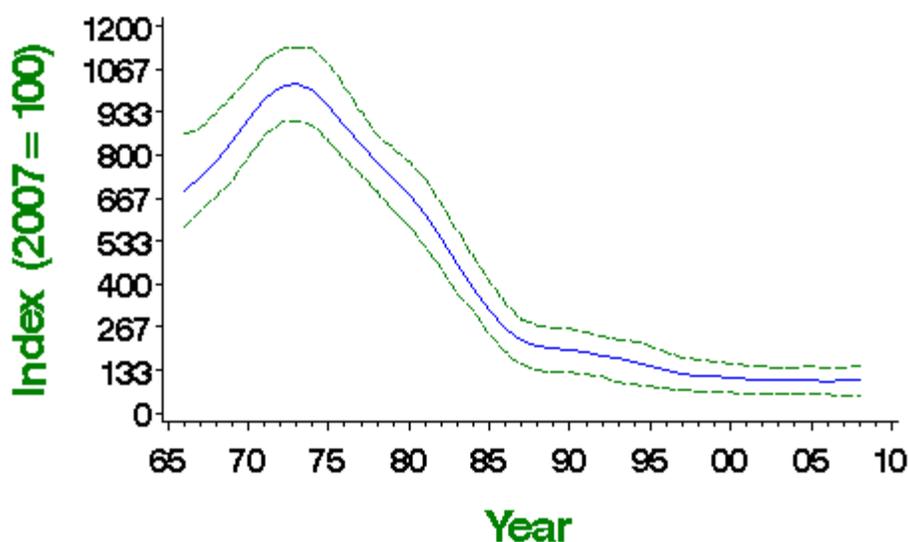

UK, England: rapid decline

**UK population size**

8,500–12,200 territories in 2000 (1988–91 Atlas estimate updated using CBC/BBS trend: [BiE04](#), [APEP06](#))

**Status summary**

Following an earlier, historical decrease, Corn Buntings declined very steeply between the mid 1970s and mid 1980s, with local extinctions across large sections of their former range. Subsequently the decline has continued, but at a much-reduced rate. Breeding performance per nesting attempt has increased considerably over this period ([Crick 1997](#)), but it is also reported that fewer birds now raise a second brood, thus reducing productivity overall ([Brickle & Harper 2002](#)). Brood size and nest survival at the chick stage are currently of NRS concern ([Leech & Barimore 2008](#)). Ring-recovery sample sizes do not permit an analysis of survival rates ([Siriwardena et al. 1998b, 2000b](#)). Any decrease there has been in survival rates is probably a result of the reduction in winter seed availability that has followed from agricultural intensification ([Donald 1997](#)). The isolated Corn Bunting population on the Western Isles is still declining rapidly, probably because agricultural change has reduced the supply of winter grain ([Wilson et al. 2007](#)). Targeted restoration of lower-intensity cultivation, but without hedgerows, might help prevent further local extinctions ([Mason & Macdonald 2006](#)). Management interventions in eastern Scotland have known potential to halt, or perhaps reverse, the Corn Bunting decline there, but their implementation is being hampered by rising grain prices and the loss of set-aside ([Perkins et al. 2008](#), [Watson et al. 2009](#)). Corn Buntings have declined rapidly across Europe since 1980 ([PECBMS 2009](#)). With declines across much of its European range, this previously 'secure' species is now provisionally evaluated as 'declining' ([BirdLife International 2004](#)).

### 3. Help on species accounts

The species in this report can be accessed in any order, but the species index and drop-down list use the taxonomic sequence established by the British Ornithologists' Union in its [British List](#). The vernacular and scientific names we use are also drawn from that list. Given this report's limited geographical scope, we have used the British rather than the international English names. Depending on the availability of data (not every species is covered by each scheme), the following will be found beneath each species heading:

- 1) **Conservation listings:** First, the European conservation category is given, according to current listings by BirdLife International in [Birds in Europe \(BirdLife International 2004\)](#). These update the original listings of [Tucker & Heath \(1994\)](#). For SPECs (Species of European Conservation Concern), the European Threat Status is also given. The current SPEC categories are as follows:

- SPEC 1** Species of global conservation concern, according to the latest assessments by BirdLife International ([www.birdlife.org/datazone/species/index.html](http://www.birdlife.org/datazone/species/index.html))
- SPEC 2** Species with an unfavourable European conservation status, and with more than half of the global breeding or wintering population concentrated in Europe
- SPEC 3** Species with an unfavourable European conservation status, but with less than half of the global breeding or wintering population within Europe

Other species, not considered to be of European conservation concern, and assessed as 'secure', have no SPEC category but are placed into two further groupings:

- Species with a favourable European conservation status, and with less than half of the breeding or wintering population within Europe (**Non-SPEC**)
- Species with a favourable European conservation status, but with more than half of the global breeding or wintering population concentrated in Europe (**Non-SPEC<sup>E</sup>**)

The UK conservation listing, given next, is taken from *The Population Status of Birds in the UK* ([Eaton et al. 2009 \(BoCC3\)](#); see [PSoB](#) pages). These supersede two previous *Birds of Conservation Concern* listings ([Gibbons et al. 1996](#), [Gregory et al. 2002](#)). There are three categories, as follows:

- Red** high conservation concern
- Amber** medium conservation concern
- Green** all other species (except introduced species, which are not classified)

The main reason or reasons for listing as red or amber are also given. NB:

- SPEC 1 (globally threatened) species are automatically red listed, and SPEC 1 (near threatened), SPEC 2 or SPEC 3 species are amber listed (unless they are introduced or a red-list criterion applies)
- Red or amber listing may stem from decline, localisation or importance of non-breeding as well as breeding populations in the UK
- Rates of population decline used to assess red and amber listing are generally derived from CBC/BBS results for the 25-year period 1981–2006 or for 1969–2006
- Range declines are generally calculated from the numbers of 10-km squares occupied in the two published [breeding atlases \(Gibbons et al. 1993\)](#) but make use of more recent material where available
- Historical decline (in UK over the period 1800–1995) is assessed by literature review

For the first time, [BoCC3](#) has undertaken to classify races, for polytypic species, where two

or more races occur regularly in the UK. On occasion the listing for a race may differ from that for the species as a whole. These race-level assessments are also given in our species pages, although we have omitted races that occur only as migrants or winter visitors.

Following the signing of the Convention on Biological Diversity at the 'Earth Summit' in Rio de Janeiro in 1992, the statutory conservation bodies in the UK compiled **Biodiversity Action Plans (BAPs)** for 26 rare or threatened bird species, of which 12 are covered by this report. A **BAP review** published in 2007 has concluded that 56 UK bird species now qualify for BAPs and has recommended that certain subspecies (e.g. Fair Isle and St Kilda Wrens) should now be included. This report covers 31 of those species.

Where a UK BAP exists, we give the link to the latest available version. You will find onward links, for example to local BAPs for that species or race. Remaining species are listed simply as 'BAP priorities'.

2) **Long-term trend:** This summarises the trend in population size since 1975 from WBS/WBBS data, 1984 from CES data, or 1967 from CBC/BBS, with reference to any CBC/BBS, WBS/WBBS or CES data that may be tabulated. If there are no data available from these schemes, any assessment of trends covers the period since about the mid 1960s, but may also take historical data into account. Increases and declines that are qualified as 'shallow', 'moderate' or 'rapid' are generally statistically significant. The following terms are used:

- **Rapid decline:** >50% population decline from CBC/BBS, WBS/WBBS or CES
- **Moderate decline:** 25–50% population decline from CBC/BBS, WBS/WBBS or CES
- **Shallow decline:** 10–25% population decline from CBC/BBS, WBS/WBBS or CES
- **Decline/Increase:** information has been derived from other sources
- **Probable/Possible increase/decline:** as above, but the information is not as certain - see the status summary for reasons
- **Stable/Fluctuating, with no long-term trend:** no overall change, or change <10%
- **Uncertain:** where the information from two monitoring schemes conflicts or if the data are unrepresentative of the species' total UK population
- **Unknown:** no information on the UK population trend is available
- **Shallow increase:** 10–50% population increase from CBC/BBS, WBS/WBBS or CES
- **Moderate increase:** 50–100% population increase from CBC/BBS, WBS/WBBS or CES
- **Rapid increase:** >100% population increase from CBC/BBS, WBS/WBBS or CES

3) **UK population size:** Periodic reports on population sizes of birds in Britain and in the UK, for the breeding season and for winter, are agreed by the Avian Population Estimates Panel (APEP), on which BTO, GCT, JNCC, RSPB and WWT are represented. Extracts from the Panel's second report (**Baker et al. 2006**) are given for each of our species, with a shortened reference (APEP06). The second edition of **Birds in Europe (BirdLife International 2004)** was published while APEP06 was in preparation. Their figures are also given, referenced as BiE04. The units and reference year (or period) is given for each estimate, and where possible its derivation is also described briefly or referenced. BiE04 and APEP06 estimates are usually identical, but may differ because:

- one or other is updated to a new reference year
- the two publications apply different rules for inclusion of introduced species
- BiE04 figures include the Channel Islands (but for most species this has no effect on the estimate)
- different methods of rounding or range estimation have been applied to the same original data
- sources used for BiE04, but not APEP06, included papers in preparation

Information too recent to have been included in either of these publications is also given, pending ratification by APEP. Readers should note that the wide ranges given for many species reflect the considerable uncertainty that applies to all but a few of the current estimates. The application of distance sampling methods to BBS data (**Newson et al. 2005, 2008**), or future surveys, including the current **2007–11 Atlas**, may well result in substantial challenge to the presently accepted figures.

4) **Status summary:** This section provides a brief summary of the trends detailed for the species and

indicates why such changes might have occurred, with reference to any published information, if this is known.

- 5) **Population trend graphs:** The first, large graph shows the most representative long-term trend in abundance for the species, and is followed after the table by further graphs from other schemes, including BBS graphs for separate UK countries, as available. If no suitable long-term trend is available then the BBS trend for the UK is shown. [Methods \(Section 2\)](#) provides details about how the trend data are calculated for each scheme. For BBS, CBC/BBS, CBC, WBS and CES, the graphs show a smoothed line (in blue) and its 85% confidence limits (in green); for the Heronries Census, annual estimates are shown in blue, 85% confidence limits in green, and a smoothed trend in red.
  
- 6) **Population trends table:** This table provides details of summarised percentage changes in population size, over the maximum period from each source, and from the past 25 years, 10 years and 5 years, where these figures are available. Further columns indicate the years included, the average number of census plots included in the analysis for each year, the percentage change (an increase if presented with no sign) and the upper and lower 90% confidence limits of that change. Where the confidence interval does not include zero change, population declines are regarded as statistically significant. The '**Alert**' column indicates where a statistically significant population decline is estimated to be of 50% or more (>50) or between 25% and 50% (>25) (see [Alerts, Section 2.8](#) for further details). The '**Comment**' column lists any caveats that must be considered when interpreting the estimates. The caveats include:
  - **Small sample:** For CBC, WBS and CES data, a mean sample size of less than 20 (but more than 10) census plots was available; for BBS data from individual countries, a mean sample of less than 40 (but more than 30) plots was available.
  
  - **Unrepresentative?:** Where joint CBC/BBS trends are reported, the trends are always considered to be representative for the region concerned. The CBC data may inadequately represent the population as a whole. This judgment was made either because the species' average abundance in 10-km squares containing CBC plots was less than that in other occupied 10-km squares, as measured by Breeding Atlas timed counts or frequency indices ([Gibbons et al. 1993](#)), or, where these figures could not be calculated, on expert opinion.
  
- 7) **Productivity graphs:** Graphs from Constant Effort Sites Scheme or Nest Record Scheme data illustrate trends in productivity. For NRS data, annual means (averages) are shown in green, with error bars to denote  $\pm 1$  standard error; quadratic or linear regression lines (in black) and the upper and lower 95% confidence limits of these lines (in blue) are also shown. For CES data, the smoothed trends are plotted (in blue) with their 85% confidence limits (in green) (see [Section 2.6](#) for details). CES survival graphs, where available, also appear in this section. For these, annual estimates are shown,  $\pm 1$  standard error, but trends have not been assessed.
  
- 8) **Productivity trends table:** This provides details of changes in productivity since 1968 (or a more recent year, depending on the availability of data). It lists the period of years concerned, the mean annual sample, the type of trend ('curvilinear' is for a significant quadratic trend, 'linear' is for a significant linear trend, 'none' is where the linear trend is not significantly different from horizontal), the modelled values (from the appropriate regression) for the first and last years and their difference (where the trend is significant), and any caveats that must be considered when interpreting the data. Changes are presented either in the units given or as percentages, and are increases unless a minus sign is shown. The caveat '**Small sample**' is given when the mean number of nest record cards contributing annually was in the range 10–30, or when the mean annual number of CES plots recording the species was less than 20 (but more than 10).
  
- 9) **Additional information:** Provides links to atlas maps and tables from previous atlas surveys, and the relevant pages of BirdFacts, BirdTrack and Garden BirdWatch, as available, from the BTO web site. Atlas maps from earlier surveys are not yet available online for Red-throated Diver, Goosander, Hen Harrier, Buzzard, Hobby and Peregrine, for which some of the original data were confidential (see [previous atlases species help](#)).

**Tip: use the 'Species quick links' box at top of each page to navigate the species pages**

## 4.1 The alert system

This report uses a system of 'alerts' that has been agreed between the providers and users of population monitoring information in the UK. ♦ The system provides alerts to population declines of 25–50% and of >50% over short, medium and longer terms (5 years, 10 years and 25+ years respectively). These help to highlight the scale and timing of declines, and act as an aid to interpreting the trend graphs presented. ♦ Our main emphasis is on long-term declines measured over the longest period available (usually 40 years) and over 25 years, which is one of the periods used to determine red and amber listing ([Eaton \*et al.\* 2009](#)). Alerts triggered over the short term for individual species should be considered as early warnings, indicating that conservation issues may be developing for these species. However, it is possible that such declines may be due to chance fluctuations in abundance from which the population is able to recover without assistance. The rapid, short-term decline of a suite of similar species should be considered as a stronger indication that potential problems may be developing. Details of the alerts and methodology used in this report are given in the [methods section](#).

These alerts are therefore important for the conservation practitioners who need to set priorities for conservation action, but we also hope that they will prove of more general use to other readers of the report. ♦ Similar [alerts for wetland birds](#) are now provided by the Wetland Bird Survey ([Maclean & Austin 2008](#)).

In this discussion we:

- 1) Review the latest population change measures and alerts for species that are on the [Birds of Conservation Concern](#) (BoCC3) [red](#) or [amber](#) lists for the UK for reasons of population decline ([Eaton \*et al.\* 2009](#)).
- 2) Identify species not on the [BoCC3](#) lists but which raise alerts on account of long-term declines, and also listed species where recovery may be sufficient to downgrade their listing status in the future.
- 3) Briefly review declines along waterways and in scrub and wetland habitats as shown by the WBS/WBBS and CES schemes.
- 4) Review trends over the last 10 years in species that have shown long-term declines, to identify the extent of ongoing declines and any evidence of recovery.
- 5) Identify those species that have shown rapid long-term population increases.
- 6) Discuss patterns of changes in breeding performance and relationships between trends in abundance and breeding performance.
- 7) Summarise the overall patterns found.

Except where otherwise indicated our discussion is based on the best long-term trend that is available for each species. These are the trends presented as the main trend graph for each species. Details of estimating and comparing trends are given in the [methods section](#). Full details of all trends available for each species are given on the [species pages](#). Summary tables of all alerts raised by each scheme are presented in the [appendices](#).

It should be noted that a number of species included in the [BoCC3](#) red and amber lists are not covered by this report. Thus tables relating to red or amber list status do not include every species so listed.

## 4.2 Latest long-term alerts

Where this section discusses conservation-listed species, it uses the now-current version of these lists, introduced in 2009 and abbreviated as **BoCC3**. The full paper ([Eaton et al. 2009](#)) details the criteria by which each listed species qualifies for its red or amber status. All of the red-listed species that breed in the UK satisfy criteria for UK decline, but amber-listed birds may be listed for reasons other than UK decline (see [Help on species accounts](#)).

### 4.2.1 Long-term trends of PSoB red-listed species

The species considered in this section are **red-listed** wholly or partly because of severe UK population declines revealed by annual census data, amounting to more than 50% either over the 25-year period 1981–2006 or, in four cases (**Skylark**, **Song Thrush**, **Marsh Tit** and **Linnet**), over the 37-year period 1969–2006. The latest long-term population changes and alerts for these severely declining species are shown in Table 4.2.1, over the maximum period available (usually the 40 years 1967–2007) and over 25 years (1982–2007). The table thus provides the first updates to the figures that were used to produce the current BoCC red list.

The 19 species in Table 4.2.1 are listed in descending order of longest-term percentage change. New to the table since the previous version of this report are **Lesser Redpoll**, **Tree Pipit**, **Yellow Wagtail** and **Cuckoo**, all amber-listed prior to 2009 but with census data that indicate a worsening decline. The figures for **Lesser Spotted Woodpecker** are likely to be a very large underestimate of the current population change, because the species had by 1999 become too rare for further annual monitoring.

For **Linnet**, **Marsh Tit** and **Skylark**, the latest 25-year change is less than 50%, indicating that, while these species meet red-list criteria, their recent rate of decline has been lower overall than for most other red-listed birds. On the data we present here, **Song Thrush** fails to meet any red-list criteria, but by the narrowest of possible margins. Its 25-year trend is for shallow decline and is not statistically significant. The 25-year trend for **Lapwing** is a significant decline of more than 50% but, as for **Lesser Spotted Woodpecker**, data quality does not allow us to be 90% confident that a decline occurred over the longer period.

**Table 4.2.1 Latest trends for red-listed species**

See [PSoB](#) pages for information on red and amber criteria

#### 4.2.2 Long-term trends of declining amber-listed species

There are 39 amber-listed species that are included in this report, of which about half (19 species) are listed because of UK population declines over the periods 1981–2006 or 1969–2006. Long-term trends are available from annual census data for 14 of these species, which are listed in Table 4.2.2 in descending order of longest-term percentage change (normally over the 40 years 1967–2007). Where available the 25-year change (1982–2007) is also shown.

**Table 4.2.2 Latest trends for declining amber-listed species**

Species	Period (yrs)	Source	Change (%)	Lower limit	Upper limit	Alert	Comment

<b>Grey Wagtail</b>	25	WBS/WBBS waterways	61	35	86		
<b>Reed Bunting</b>	40	CBC/BBS UK	-18	-38	7		
<b>Reed Bunting</b>	25	CBC/BBS UK	21	-3	50		

See [PSoB](#) pages for information on red and amber criteria

Three species raise high alerts, having shown significant declines of greater than 50%. **Whitethroat** shows a massive decline over the 40-year period, since this includes the extraordinary population crash that occurred between 1968 and 1969, but the 25-year period since 1982 has seen a partial reversal of this decrease. English **Willow Warblers** meet the red-list criterion for population decline, but it is likely that the overall UK decline has been less severe: Scottish and Welsh trends are less clear, but show significant declines over the ten-year period to 2007. **Redshank** has declined steeply in lowland Britain, according to waterways surveys, raising high alerts; a major decline is also documented for its breeding sites on saltmarsh, and BBS data suggest that decline has occurred across a wide range of habitats. Our best estimate of long-term change in the English **House Martin** population also shows a decline of more than 50%, but statistically it is not significantly different from no change and therefore no alerts are raised for this species. This species is best regarded as data deficient, but may possibly be a future candidate for red listing. BBS data indicate that its numbers have been changed little since 1994, however.

**Bullfinch** was moved from the red to the amber list at the 2009 review. Its 40-year trend is only marginally below the red-list threshold, but the 25-year trend, although significant, is not large enough to raise any alert. **Common Sandpiper**, **Meadow Pipit** and **Mistle Thrush** continue to meet amber-list decline criteria in both periods. Data for **Nightingale**, **Little Grebe** and **Curlew** suggest a similar overall rate of decline but should be treated with caution, as the confidence intervals are very wide. For **Little Grebe** there is poor agreement since 1994 between WBS/WBBS data and BBS, which may cover a more representative set of habitat types for this species: BBS results show a non-significant increase.

Populations of **Dunnock**, **Grey Wagtail** and **Reed Bunting** are recovering and show stable or increasing trends over the shorter, 25-year period. Reed Bunting now shows only a shallow decline over the 40-year period and has ceased to raise any alerts for population decline.

#### 4.2.3 Long-term declines of species that are not currently red or amber listed (for declines)

This section of the report draws attention to declines which apparently surpass red or amber criteria but which are not recognised in the current listings. Even though a review of the red and amber lists has just taken place in 2009, there are a few species that remain in this category (Table 4.2.3).

**Table 4.2.3 Long-term trends for declining species not on the red or amber list (for declines)**

Species	Period (yrs)	Source	Change (%)	Lower limit	Upper limit	Alert	Comment
<b>Woodcock</b>	31	CBC to 1999	-74	-88	-49	>50	Small sample
<b>Woodcock</b>	25	CBC to 1999	-76	-88	-51	>50	Small sample
<b>Little Owl</b>	40	CBC/BBS UK	-46	-68	-16	>25	
<b>Little Owl</b>	25	CBC/BBS UK	-48	-62	-29	>25	
<b>Dipper</b>	32	WBS/WBBS waterways	-30	-45	-7	>25	

See [PSoB](#) pages for information on red and amber criteria

**Woodcock** is currently amber-listed solely because it is a Species of European Conservation Concern (SPEC category 3) through its moderate decline on the European scale ([BiE04](#)). The only UK census data indicating a trend are from CBC, which recorded steep declines. Samples were small, however, and the CBC's mapping method was not well suited to monitoring this species: for these reasons, the CBC trend is no longer used to support the species' conservation listing.

**Little Owl** meets amber-list criteria for population decline but, as an introduced species, is not eligible for any conservation listing. Although the trends are statistically significant, it should be borne in mind that neither CBC nor BBS census techniques cater well for nocturnal and crepuscular species.

Fluctuations in the UK **Dipper** population since 1974 appear to be underlain by decrease. The current estimate of long-term change, for the first time employing WBBS as well as WBS data, is of more than 25% decline and so raises a new alert.

#### 4.2.4 Declines along linear waterways

The [Waterways Bird Survey](#) and [Waterways Breeding Bird Survey](#) supplement the results from CBC and BBS, which are more broadly based surveys, by measuring trends in the bird populations alongside rivers and canals. Joint WBS/WBBS trend are now available, allowing trend assessment to be continuous since 1974 for around 24 of the species that were covered by WBS. WBBS, ongoing since 1998, includes all bird species. A full set of up-to-date waterways trends can be obtained from the [Table generator](#) section of this report.

For several species, such as **Canada Goose**, **Goosander** and **Kingfisher**, that are abundant in waterway habitats, the WBS/WBBS trend provides our headline information on population trends. For **Redshank**, **Common Sandpiper**, **Little Grebe**, **Grey Wagtail** and **Dipper**, which are also in this category and are in decline, details appear in Tables 4.2.2 or 4.2.3, as appropriate. Where WBS/WBBS is not the headline trend for a species, however, the waterways data nevertheless provide valuable supplementary information from this sensitive habitat.

Table 4.2.4 lists all statistically significant declines of greater than 25% recorded from the full period of waterway monitoring (nominally 1975–2007). It does not include Little Grebe, for which the decline is not statistically significant (Table 4.2.2). Four species are included for which WBS/WBBS is not the headline trend and so are not listed in Tables 4.2.2 or 4.2.3.

**Table 4.2.4 Population declines of greater than 25% recorded by the Joint Waterways Bird Survey (WBS/WBBS) between 1975 and 2007**

Species	Period (yrs)	Source	Change (%)	Lower limit	Upper limit	Alert	Comment
<a href="#">Yellow Wagtail</a>	32	WBS/WBBS waterways	-94	-98	-90	>50	
<a href="#">Pied Wagtail</a>	32	WBS/WBBS waterways	-61	-70	-52	>50	
<a href="#">Reed Bunting</a>	32	WBS/WBBS waterways	-59	-71	-42	>50	
<a href="#">Redshank</a>	32	WBS/WBBS waterways	-56	-88	-21	>50	
<a href="#">Sedge Warbler</a>	32	WBS/WBBS waterways	-41	-60	-20	>25	
<a href="#">Common Sandpiper</a>	32	WBS/WBBS waterways	-36	-52	-23	>25	
<a href="#">Dipper</a>	32	WBS/WBBS waterways	-30	-45	-7	>25	
<a href="#">Grey Wagtail</a>	32	WBS/WBBS waterways	-26	-42	-7	>25	

The trends for **Yellow Wagtail** and **Reed Bunting** are consistent in direction with the 40-year trends reported from CBC/BBS, but in each case the declines on waterways have been more severe. Reed Bunting recovery along waterways has also been weaker than in the countryside as a whole. The **Pied Wagtail** declines along waterways, which are significant in all the periods assessed, are intriguing

because they contrast markedly with the fluctuating but generally upward trend as measured by CBC/BBS. The cause of the decline along waterways is currently unknown.

For **Sedge Warbler**, the headline trend is a non-significant 40-year decrease of 24% from CBC/BBS. Large fluctuations make trends difficult to determine in this species, but the WBS/WBBS data add firmer evidence for a long-term moderate decrease.

A full set of alerts raised by WBS/WBBS, and long-term increases detected by that index, are tabulated in [section 7.2](#).

#### 4.2.5 Declines on CES plots

The **Constant Effort Sites Scheme** provides trends from standardised ringing in scrub and wetland habitats. It is possibly our best scheme for monitoring some bird populations inhabiting reed beds but its main objective is to collect integrated data on relative abundance, productivity and survival for a suite of species. The longest trends currently available from the CES cover a period of 23 years (Table 4.2.5).

**Table 4.2.5 Population declines of greater than 25% recorded by the Constant Effort Sites Scheme between 1984 and 2007**

Species	Period (yrs)	Source	Change (%)	Lower limit	Upper limit	Alert	Comment
<a href="#">Lesser Redpoll</a>	23	CES adults	-98	-100	-96	>50	Small sample
<a href="#">Linnet</a>	23	CES adults	-94	-98	-85	>50	
<a href="#">Yellowhammer</a>	23	CES adults	-81	-94	-59	>50	Small sample
<a href="#">Willow Warbler</a>	23	CES adults	-65	-73	-59	>50	
<a href="#">Lesser Whitethroat</a>	23	CES adults	-62	-80	-38	>50	
<a href="#">Willow Tit</a>	23	CES adults	-56	-86	-26	>50	
<a href="#">Reed Bunting</a>	23	CES adults	-56	-69	-42	>50	
<a href="#">Whitethroat</a>	23	CES adults	-46	-61	-30	>25	
<a href="#">Sedge Warbler</a>	23	CES adults	-43	-60	-26	>25	
<a href="#">Reed Warbler</a>	23	CES adults	-37	-51	-22	>25	

Most of the species that are declining on CES sites show broadly similar trends to those from CBC/BBS or WBS/WBBS data. **Lesser Redpoll**, **Linnet**, **Yellowhammer** and **Willow Tit** are red listed on the strength of their CBC/BBS declines (Table 4.2.1). Similarly, **Willow Warbler**, **Reed Bunting**, and **Whitethroat** are amber listed.

For reasons unknown, CES trends for **Lesser Whitethroat**, **Sedge Warbler** and **Reed Warbler** are considerably more negative than those from census data. Both CBC/BBS and WBS/WBBS show strong increases for **Reed Warbler**, in clear contrast to the CES data.

A full set of alerts raised by CES, and long-term increases detected by that scheme, are tabulated in [section 7.3](#).

[Return to previous page](#)

[Next page – 4.3 Ten-year trends and evidence of species recovery](#)

### 4.3 Ten-year trends and evidence for species recovery

If the status of species that have shown long-term declines were now improving, we would expect to find trends to be more positive in recent years compared with the earlier part of the time series. To examine this, we list in Table 4.3.1 the best change estimates over the most recent ten-year period for which we have data (1997–2007) for all of the declining species listed in Tables 4.2.1–4.2.3 ([section 4.2](#)).

The table also includes seven further species which are listed in [BoCC3](#) because of recent breeding decline, for which we can report ten-year trends but which lack monitoring series covering longer periods. These are **Grasshopper Warbler** and **Wood Warbler** (both red listed), and **Red Grouse**, **Snipe**, **Swift**, **Whinchat**, and **Pied Flycatcher** (all amber listed).

See [PSoB](#) pages for information on red and amber criteria

The 43 species listed include 21 from the red list, 19 declining species that are amber listed on account of population declines and three species (**Woodcock**, **Little Owl** and **Dipper**) whose declines, for reasons explained in [section 4.2](#), are not recognised by either red or amber listing. **Woodcock** shows both range contraction and population decline in the UK but is amber listed only for its broader decline across Europe. **Little Owl**, as an introduced species, is not eligible for a conservation listing. The **Dipper** population in the UK has been fluctuating since 1974 but new information since [BoCC3](#) (the addition of WBBS data into the trend) has accentuated an underlying decrease.

Species are listed in ascending order of population change. Thus the species with steep recent decline appear first, followed by those with shallower change. Towards the foot of the table are species that remain in long-term decline but have shown partial recovery of those losses during the recent ten-year period. For **Lesser Spotted Woodpecker** and for **Woodcock**, both now too scarce for annual monitoring to continue, the ten-year period for which data are tabulated is 1989–99.

As indicated at the top of Table 4.3.1, there is high confidence that the populations of both **Willow Tit** and **Turtle Dove** have halved in the last ten years alone (1997–2007). A further 15 species continue to raise alerts, also having declined significantly by more than 25% in this ten-year period. All these declines compound earlier losses for these species. The ongoing declines of so many of the species listed in Table 4.3.1 must be a cause of serious conservation concern.

The 25% threshold which is used to define decreases over the 25-year period that are worthy of amber listing equates to a change of 10.9% over ten years, assuming a constant rate of change. Rounding this to 11%, a decrease of 11% or greater indicates that, on the last ten years' results, the species is still on course for red or amber listing. A more positive change than -11% indicates that the population decline may be easing off. Species that have declined in the past but with a change smaller than 11%, or no measurable population change, over the ten-year period are **Skylark**, **Yellowhammer**, **Mistle Thrush**, **Lapwing**, **Bullfinch**, **Little Grebe**, **Meadow Pipit** and **House Martin**.

Seven species at the foot of the table show clear positive trends over the last ten years. Despite its recent increase, the long-term decline of **Whitethroat** was recognised in 2009 by the move of the species from the green to the amber list. Whitethroat numbers have increased steadily since the mid 1980s but are still far below the population level prior to the 1968/69 crash. **Tree Sparrow** and **Song Thrush** remain on the red list, and **Dunnock**, **Grey Wagtail** and **Snipe** on the amber list, because their recent increases also represent only a small recovery from earlier losses. The increase in Tree Sparrow numbers is very welcome but is coming from such a low level that numbers remain far below those of the mid 1970s, with the population trend graph still showing little sign of a clear recovery. Similarly while the BBS shows a 31% increase in Snipe over the last ten years, much of the species' former range across lowland Britain lost since the 1960s remains unoccupied. Because of its recent steep upturn, however, **Reed Bunting** was moved in 2009 from the red to the amber list.

#### 4.4 Increasing species

Population changes of species for which our best trend estimate from CBC/BBS (usually over 40 years) or from WBS/WBBS (usually over 32 years) shows an increase of more than 50% are shown in Table 4.4.1, below. There are 28 species listed, of which three are new since last year. The new WBS/WBBS trend for **Tufted Duck** considerably strengthens the increase apparent earlier on WBS plots alone, although the confidence interval remains wide. The inclusion of **Reed Warbler** depends on the resolution of conflict between CES data, which show decrease, and census results, which show increase and now produce the headline trend for this species. **Goldcrest** is well known for its wide variations in population level: its abundance in 2007 justifies its inclusion in this year's table, but has already been overtaken by a population crash following cold weather early in 2009.

There are 19 species that have more than doubled their population size over the decades under review. **Tufted Duck**, **Reed Warbler**, **Canada Goose** and **Wren** have moved into this category since the previous report, and **Oystercatcher** and **Goosander** have been lost, with their percentage increases dropping below 100%. The fastest-increasing species in this report are, however, not included in Table 4.4.1, because their monitoring data cover too short a period. Both are introduced, and could be viewed as conservation problems rather than successes. The population of **Ring-necked Parakeet** is estimated to have risen by 600% over the 12 years 1995–2007, and that of **Greylag Goose** by 430% over the 14-year period 1993–2007.

Four groups stand out among the increasing species: corvids – **Carrion Crow**, **Magpie** and **Jackdaw**; doves – **Collared Dove**, **Stock Dove** and **Woodpigeon**; insectivores; and some waterbirds. Corvids appear to have benefited from the decrease of predator control by gamekeepers in recent years, and the increased use of brassica crops (particularly oilseed rape) has probably been beneficial to the larger doves.

The majority of increasing insectivores are woodland species that are also common in gardens: **Great Spotted Woodpecker**, **Green Woodpecker**, **Nuthatch**, **Blackcap**, **Great Tit**, **Wren**, **Long-tailed Tit** and **Coal Tit**. The reasons for these increases are presently unclear. **Pied Wagtail** has increased in numbers by 79% on CBC/BBS plots over 40 years, but declined by 61% on WBS/WBBS plots over the past 32 years. The former survey is likely to be more representative of the UK population as a whole. The increase in **Pheasants** is driven largely by the hugely increasing scale of releases for shooting.

**Table 4.4.1 Long-term population increases of greater than 50% from CBC/BBS (1967-2007) or WBS/WBBS (1975-2007) using the best survey for each species**

<b>Goldcrest</b>	40	CBC/BBS England	52	-11	220		

A number of species associated with freshwater habitats are also becoming more abundant, although differences between their ecological requirements make it unlikely that a common causal factor is involved. For **Mallard**, the CBC/BBS increase was matched by a WBS increase of 206% over 32 years. The growth of this population is still continuing, with CBC/BBS recording a 15% increase over the most recent ten-year period. The increases recorded for **Mute Swan** on both CBC/BBS and WBS plots are likely to be the result of banning the use of lead weights by anglers. **Oystercatchers** have increased by 92% on WBS/WBBS plots over the last 32 years. This finding is consistent with the results of the most recent survey of **Breeding Waders of Wet Meadows** which found that numbers of Oystercatchers using these habitats in England and Wales increased by 51% between 1982 and 2002. **Grey Heron** is not listed in Table 4.4.1 because it is covered by a separate survey that spans a much longer period. The population of this species is not increasing as fast as the species listed in the table, with only a 16% increase over the last 25 years. Nevertheless this population has undergone a sustained increase of 57% over the last 78 years (1929–2007).

Two widespread raptors have shown remarkable recoveries from low population levels caused by pesticides in the 1950s and 1960s, assisted by a relaxation of predator control. **Buzzards** increased by a remarkable 444% between 1967 and 2007, with a rapid increase of 36% over the last ten years alone. **Sparrowhawks**, too scarce for CBC to monitor until the mid 1970s, showed a 164% increase over the 32-year period from 1975 to 2007. However, their recovery appears to have been completed earlier than for **Buzzard**, with the population having been relatively stable since the early 1990s.

[Next page – 4.5 Changes in breeding performance](#)

[BBWC Home](#) > [Contents](#) > [Discussion](#) > [Changes in breeding performance](#)

## 4.5 **Changes in breeding performance**

Changes in a range of aspects of breeding performance can be measured under the **Nest Record Scheme** (NRS) and the **Constant Effort Sites** (CES) scheme. The NRS provides information on components of breeding performance per nesting attempt (clutch size, brood size and failure rates at the egg and nestling stages) that can be combined to give an overall estimate of the number of Fledglings produced Per Breeding Attempt (FPBA) – see [section 2.7](#) for further information. The CES scheme provides an index of breeding performance accrued over all nesting attempts in a particular year – see [section 2.6](#). CES results also take changes in the survival rates of fledglings in the first few months after leaving the nest into account, a period when losses of young can be high.

Breeding performance may be influenced by a variety of factors, including food availability, predation pressure and weather conditions. Variation in breeding performance may help to influence fluctuations in abundance and may even be the main demographic factor responsible for determining the size of the population. Conversely, the breeding performance of a population may be negatively related to its size, with productivity decreasing as the number of individuals increases, and vice versa. This relationship may be due to the action of density-dependent factors, such as competition for resources: as numbers increase, competition for resources is likely to increase, possibly resulting in poorer productivity. Alternatively, increases in abundance may be accompanied by range expansion into new, suboptimal habitats where breeding performance is poorer, thus reducing the average productivity of the population. The converse is also true, and where declines result from the loss of individuals from these suboptimal habitats, there may be a subsequent increase in average productivity.

### 4.5.1 Changes in Fledglings Per Breeding Attempt from Nest Record Scheme data

The NRS started collating nest histories of individual breeding attempts in 1939 and sufficient data are available for trends to be produced from the mid 1960s onwards. Previous reports have explored annual variation in clutch size, brood size and stage-specific nest failure rates, and the summary tables for these breeding parameters can all be found in [section 7.5](#). While detailed exploration of annual variation in productivity is essential if the impacts of environmental impacts on breeding success are to be fully understood, the combined effects of concurrent changes in the number of offspring and failure rates can be difficult to interpret. For the current report, we have therefore introduced a new statistic, Fledglings Per Breeding Attempt (FPBA; [Siriwardena et al. 2000b](#), [Crick et al. 2003](#)), which is designed to integrate these measures into a single figure representing the mean number of young leaving each nest in a given year.

All species displaying significant temporal trends in the mean number of FPBA are included in Table 4.5.1; trends in the individual reproductive parameters are summarised in [section 7.5](#). In total, 33 species exhibited significant trends in FPBA, of which eight were negative over the past 20 years or more, indicating that reproductive output has decreased over time, including four BoCC Red-listed species ([Nightjar](#), [Spotted Flycatcher](#), [Linnet](#), [Yellowhammer](#)), three Amber-listed species ([Bullfinch](#), [Reed Bunting](#), [Dunnock](#)) and one Green-listed species ([Chaffinch](#)). While productivity of [Nightjar](#), [Reed Bunting](#) and [Linnet](#) has been falling since the start of the NRS time series in the mid 1960s, declines in breeding success of the remaining five species have occurred over the last 15–20 years.

There is increasing evidence that lower trophic levels are responding to climatic change more rapidly than those towards the top of the food chain ([Visser & Both 2005](#), [Thackeray et al. in press](#)) Resulting mismatches in the relative timing of food availability and offspring, referred to as phenological disjunction, that can have severe impacts on breeding success and ultimately on population trends ([Both et al. 2009](#)). The model species most frequently used in European studies are [Great Tit](#) and [Pied Flycatcher](#), which are both dependent on a relatively short period of a caterpillar availability to provide food for their nestlings. As springs have become warmer, oak leafing dates have advanced – a shift matched by caterpillars ([Buse et al. 1999](#)) but not by tits ([Visser et al. 1998](#)) or flycatchers ([Both et al. 2009](#)). This situation can apply to any species dependent on a food resource that is limited to a relatively short period of availability, and particularly to migrants, which may be constrained from advancing their laying dates by the energetic demands of their journey northwards from the wintering grounds. Of the species listed in Table 4.5.1, [Nightjar](#), [Spotted Flycatcher](#) and [Chaffinch](#) are likely to be the most reliant on the availability of Lepidoptera larvae or adults and may therefore be subject to issues of

disjunction, although none are as dependent on individual species of invertebrate as tits or **Pied Flycatchers**. **Nightjar** and **Spotted Flycatcher** may also be experiencing negative impacts of climate change in their African wintering grounds, where reduced rainfall could lead to a fall in insect abundance and a subsequent loss of condition, resulting in a lower reproductive output in the following spring ([Saino et al. 2004](#)).

Recent declines in the number of aerial insects, particularly moths ([Conrad et al. 2006](#)), have been reported across the UK and these may impact on the productivity of nesting attempts of **Nightjar** and **Spotted Flycatcher** by reducing food availability for both parents and offspring. Declining food availability may also be an issue for the other species displaying negative trends in FPBA. Reduced access to winter stubbles due to changes in farming practices have been linked to declines in survival rates of **Reed Bunting** and **Yellowhammer**, resulting in population declines ([Siriwardena et al. 1998b](#), [Peach et al. 1999](#), [Siriwardena et al. 2000b](#)). If adults of these species and of other stubble feeders such as **Linnet** are in poorer condition at the start of the breeding season, their investment in reproduction may be reduced. Investigations into **Linnet** declines using BTO data sets have indicated that population declines observed for this species are driven by a fall in productivity ([Siriwardena et al. 1999](#), [2000b](#)). Causes of declines in the breeding success, and indeed the population declines, of **Dunnoek** and **Bullfinch** are still unclear despite a significant number of demographic studies ([Siriwardena et al. 1998a](#), [1999](#), [2000b](#), [2001](#), [Proffitt et al. 2004](#)). A general decline in the quality of scrub and woodland habitats, possibly mediated at least in part by browsing by increasing numbers of deer ([Fuller et al. 2005](#)), may have reduced the availability both of food and of high-quality nesting sites.

Increases in egg-stage failure rate are evident across all eight species exhibiting negative FPBA trends ([Table 7.5.3](#)), with a further five exhibiting declines in nestling failure rates (**Dunnoek**, **Spotted Flycatcher**, **Linnet**, **Bullfinch**, **Yellowhammer** – [Table 7.5.4](#)), indicating that the incidence of whole nest failures is increasing over time. One factor that could be responsible is an increase in predation pressure, either due directly to an increase in predator abundance or to a decline in the availability of suitable nesting sites due to habitat degradation. While there is good evidence to suggest that corvids, **Sparrowhawks** and Grey Squirrels are all increasing in number and that these species may have a negative influence on avian abundance at a very localised scale (e.g. [Groom 1993](#), [Stoate & Szcuz 2001](#), [2006](#)), previous studies have failed to find any evidence of a significant impact at a national scale ([Gooch et al. 1991](#), [Thomson et al. 1998](#), [Chamberlain et al. 2009](#), [Newson et al. 2009](#)). Further research into the impacts of nest predators on population trajectories, at a variety of spatial scales, is urgently required.

Increasing human activity in the wider countryside, resulting from a growing population, could also increase disturbance levels, which could in turn influence the rates of predation and desertion. A recent investigation of **Nightjar** productivity suggested that nest failure is most likely in areas heavily frequented by walkers and dogs ([Langston et al. 2007](#)).

**Table 4.5.1**

### Significant trends in Fledglings per breeding attempt measured between 1968-2007

Species	Period (yrs)	Mean annual sample	Trend	Predicted in first year	Predicted in last year	Change	Comment

See [Help](#) for help with interpretation

#### 4.5.2 Changes in productivity from Constant Effort Scheme ringing data

The CES started monitoring populations in 1983, so the changes in productivity shown in Table 4.5.2 cover roughly half the time period of the Nest Record Scheme results. The CES data set is unique in providing relative measures of adult abundance and productivity from the same set of sites in wetland and scrub habitats. While the NRS data set monitors the productivity of individual nesting attempts, the proportion of juveniles in the CES catch provides a relative measure of annual variation in productivity that integrates the effects of the number of fledglings produced per attempt, number of nesting attempts and immediate post-fledging survival. Use of these two techniques in combination provides a powerful method of determining which factors are responsible for observed declines in recruitment of young birds into the breeding population.

Overall, 13 species exhibit declines of greater than 20% in the proportion of juveniles captured, of which seven ([Nightingale](#), [Sedge Warbler](#), [Blue Tit](#), [Linnet](#), [Lesser Redpoll](#), [Goldfinch](#) and [Reed Bunting](#)), all exhibit declines in the proportion of juveniles captured over the last 20 years of greater than 50%, although it should be noted that [Nightingale](#) and [Lesser Redpoll](#) both occur on a relatively small number of plots. A further four species show reductions in relative productivity of between 24% and 50%: [Blackbird](#), [Song Thrush](#), [Blackcap](#), [Garden Warbler](#), [Willow Warbler](#) and [Great Tit](#). Productivity declines in both [Linnet](#) and [Reed Bunting](#) have also been identified using the NRS dataset, suggesting that these trends may be driven by declines in the productivity of individual attempts rather than changes in the number of breeding attempts made or in post-fledging survival rates.

Of these 13 species, seven ([Nightingale](#), [Song Thrush](#), [Sedge Warbler](#), [Willow Warbler](#), [Linnet](#), [Lesser Redpoll](#) and [Reed Bunting](#)) have experienced significant population declines, either on CES sites or more widely (based on CBC/BBS figures). For [Linnet](#) there is good evidence that variation in productivity has been important in driving the decline ([Siriwardena et al. 2000b](#)), but for [Song Thrush](#), [Willow Warbler](#) and [Reed Bunting](#) other work indicates that variation in survival rates is likely to have been a more important contributor to population changes ([Peach et al. 1995a, 1999](#), [Robinson et al. 2004](#), [Baillie et al. 2009](#)). The large decline in [Nightingale](#) productivity may have contributed to the complex changes in its distribution shown by the 1999 survey, which identified decreases in abundance over large parts of the species' range. The six other species ([Blackbird](#), [Blackcap](#), [Garden Warbler](#), [Great Tit](#), [Blue Tit](#), and [Goldfinch](#)) demonstrating marked reductions in productivity on CES sites have not experienced related declines in abundance, either on CES sites or more widely. These productivity declines may be driven by density-dependent processes, whereby increased competition for resources in an expanding population reduces the mean breeding success per pair.

**Table 4.5.2**

## Changes in productivity indices (percentage juveniles) for CES 1984-2007 (23 years) calculated from smoothed trend

Species	Period (yrs)	Plots (n)	Change (%)	Lower limit	Upper limit	Comment
Nightingale	23	12	-92	-100	-19	Small sample
Lesser Redpoll	23	18	-88	-98	-46	Small sample
Linnet	23	23	-73	-94	-21

### 4.5.3 Changes in average laying dates from Nest Record Scheme data

Over the past 25 years, many species have exhibited a trend towards progressively earlier clutch initiation ([Crick \*et al.\* 1997](#)) with laying dates showing curvilinear responses over the past 50 years as spring temperatures have cooled and then warmed ([Crick & Sparks 1999](#)). Table 4.5.3 confirms that over the past 39 years the majority of species exhibiting significant trends show an advancement of laying dates rather than a delay. Thus 43 species are laying between 4 and 30 days earlier, on average, than they were 39 years ago, with [Grey Wagtail](#), [Pied Flycatcher](#), [Starling](#) and [Corn Bunting](#) added to the list in 2009. [Pied Flycatcher](#) is a particularly notable addition as it is a focal species for European researchers investigating the impacts of climate change on birds: it has been included for the first time in the current report thanks to the efforts of volunteer inputters who have now computerised over 5,000 historic records. There are no taxonomic or ecological associations between the species showing such changes, and they seem to occur across a wide range of species ([Crick \*et al.\* 1997](#)).

The significance of the changes in phenology for breeding performance not well understood but has stimulated a large number of scientific studies, including several ongoing projects at BTO. Earlier average laying may be beneficial for birds because earlier fledging is often related to improved survival to the following year – early-nesting parents have an increased chance of having their offspring recruited into the next generation ([Visser \*et al.\* 1998](#)). However, the timing of leaf emergence and the speed of caterpillar development is also changing under increased temperatures ([Buse \*et al.\* 1999](#), [Visser & Holleman 2001](#)) and the results of several recent studies have suggested that some birds may be unable to advance their phenology sufficiently to match phenological changes in their food supply, such that later-nesting birds are suffering from poorer productivity. [Both \*et al.\* \(2006\)](#) demonstrated that mismatches between periods of food availability and chick demand can affect abundance in Dutch [Pied Flycatcher](#) populations, with those demonstrating the largest mismatches between arrival in spring and peak caterpillar abundance exhibiting the greatest declines. As a consequence of climate change there may be an increasing mismatch between predator activities and the availability of their food supplies at different trophic levels within ecosystems ([Both \*et al.\* 2009](#)). The conservation significance of such phenological disjunction remains an active research area with potentially important policy implications for conservation.

Only two species, [Skylark](#) and [Yellowhammer](#), exhibit significant trends towards later laying. A recent collaboration between BTO and Aberdeen University used NRS data to identify an increase in the frequency of repeat brooding in [Yellowhammers](#) ([Cornulier \*et al.\* 2009](#)) which, as mean laying dates are calculated across all broods, would result in the observed shift. Increased production of repeat broods could be stimulated by climatic amelioration, with later nests being more productive in warmer

conditions, or by movement of populations away from farmland and into habitats where they are released from constraints on multiple brooding. Previous research into multiple brooding in [Skylark](#) populations has demonstrated that increased planting of autumn-sown cereals has restricted the potential for repeat nesting attempts ([Chamberlain & Siriwardena 2000](#)), but this species may also increasingly have moved to alternative habitats.

It is likely that the laying dates of the majority of those species that do not show a significant trend in timing of laying are also related to weather, but that their weather-mediated cues do not show any trend over time ([Crick & Sparks 1999](#)).

Table 4.5.3

### Significant trends in Laying date measured between 1968-2007

Species	Period (yrs)	Mean annual sample	Trend	Predicted in first year	Predicted in last year	Change	Comment
<a href="#">Magpie</a>	39	35	Linear decline	Apr 24	Mar 25	-30 days	
<a href="#">Grey Heron</a>	39	26	Linear decline	Apr 8	Mar 10	-29 days	Non-breeders include
<a href="#">Long-tailed Tit</a>	39	45	Linear decline	Apr 21	Apr 6	-15 days	
<a href="#">Greenfinch</a>	39	95	Linear decline	May 25	May 10	-15 days

## 4.6 Conclusion

We hope that this report will be useful as a ready source of information for conservation practitioners, and as a source of information for those involved in more strategic conservation policy making, as well as to the general student of bird populations. The information presented here is a summary of a very extensive and much more detailed data set held by the BTO. This report provides a relatively simple and concise overview of the way in which populations are changing, suggesting areas where further research is required or conservation action needs to be taken.

Alerts are raised as a result of declines in the population sizes of a considerable number of species. These alerts will help conservation organisations to prioritise future conservation action, alongside the Birds of Conservation Concern list ([Eaton \*et al.\* 2009](#)) and other information.

The information concerning demographic factors contained in this report will also help conservation organisations to target their resources more effectively. For declining species of conservation importance, declines in breeding performance may indicate that conservation action should be targeted towards the breeding season; such responses may sometimes be masked, however, by density-dependent improvements in breeding success as the population declines ([Green 1999](#)). The lack of a decline in breeding performance may suggest that factors other than nesting success, such as loss of habitat or changes in survival rates are more likely to be influencing the observed population declines. A report of this kind can provide only an initial summary of such information, and a full assessment of the population dynamics of a declining species will generally require more detailed investigations (e.g. [Peach \*et al.\* 1999](#), [Freeman & Crick 2003](#), [Robinson \*et al.\* 2004](#)).

Finally, we hope that users of this report will provide feedback on how the report can be improved. We will welcome comments on any aspect of this report, as they will help us to produce a better and more useful next edition.

## 5. Acknowledgements

### Volunteer fieldwork

Our biggest thankyou is to the volunteers who collected the data on which this website is based. The population trends and other results that we present rely on the sustained, long-term fieldwork of many thousands of BTO volunteers. Our knowledge of the conservation status of the UK's bird populations is possible only as a result of their dedication and enthusiasm. The conservation community owes them an enormous debt of gratitude for their work. We are also very grateful to the many farmers, land managers and landowners who permitted census work, nest recording and ringing to take place on their land.

### Report production and analysis

This website presents the latest in a series of reports, prepared within the partnership between the British Trust for Ornithology (BTO) and the Joint Nature Conservation Committee (JNCC) (on behalf of Natural England, Scottish Natural Heritage, the Countryside Council for Wales and the Northern Ireland Environment Agency), as part of its programme of research into nature conservation.

Mr and Mrs J A Pye's Charitable Settlement provided additional support towards the development of the website.

This report includes results from the Breeding Bird Survey, which is funded jointly by BTO, JNCC and RSPB. The BBS partners are very grateful to the Environment and Heritage Service in Northern Ireland (now Northern Ireland Environment Agency) and to the Royal Society for the Protection of Birds in Scotland for supporting professional surveys in areas that would otherwise be difficult to cover.

Helen Baker and Ian McLean of JNCC provided helpful discussions, comments and support during the production of the report. David Stroud, Rowena Langston, David Gibbons, Jacquie Clark, Nigel Clark, Jeremy Greenwood and Malcolm Vincent provided helpful comments on earlier editions of this publication.

The analyses would not have been possible without the hard work of many past and present BTO staff who have organised schemes, collated data sets or overseen analyses, including: Sue Adams, Dawn Balmer, Jeremy Blackburn, Jacquie Clark, Mark Collier, Rachel Coombes, Humphrey Crick, Steve Freeman, Bridget Griffin, Mike Raven, Brenda Read, Richard Thewlis, Anne Trewhitt and Jane Waters. The work is also heavily dependent on the BTO's computer and database systems overseen jointly by Karen Wright (with Iain Downie). Susan Waghorn exercised great skill and effort in helping to design and build the website. The site is now maintained by Mandy Andrews and Laura Smith.

We are very grateful to all of the above organisations and individuals for their contributions to this report.

### Section 6 – References

## REFERENCES

Clicking on the short form of any reference in the text of this report will bring you to its full details in this section: the reference sought will be at the very top of your view. Where possible, we provide an onward link either to an abstract or, where it is freely available, to the full text. Alternatively, your own web search will often take you to the summary of an article and the opportunity to purchase the text in full.

Most of the listed publications are available in printed form to BTO members and other bona fide researchers through the [Chris Mead Library](#) at BTO headquarters in Thetford.

## 7. Appendix – Summary tables of changes in population size and breeding performance

### 7.1 Tables of alerts and population increases from CBC/BBS

- 1a. [CBC/BBS UK alerts – 40 years](#)
- 1b. [CBC/BBS England alerts – 40 years](#)
- 2a. [CBC/BBS UK alerts – 25 years](#)
- 2b. [CBC/BBS England alerts – 25 years](#)
- 3a. [CBC/BBS UK alerts – 10 years](#)
- 3b. [CBC/BBS England alerts – 10 years](#)
- 4a. [CBC/BBS UK alerts – 5 years](#)
- 4b. [CBC/BBS England alerts – 5 years](#)
- 5a. [CBC/BBS UK population increases of >50% – 40 years](#)
- 5b. [CBC/BBS England population increases of >50% – 40 years](#)

### 7.2 Tables of alerts and population increases from WBS/WBBS

1. [WBS/WBBS alerts – 32 years](#)
2. [WBS/WBBS alerts – 25 years](#)
3. [WBS/WBBS alerts – 10 years](#)
4. [WBS/WBBS alerts – 5 years](#)
5. [WBS/WBBS population increases of >50% – 32 years](#)

### 7.3 Tables of alerts and population increases from CES

1. [CES adults alerts – 23 years](#)
2. [CES adults alerts – 10 years](#)
3. [CES adults alerts – 5 years](#)
4. [CES adults population increases of >50% – 23 years](#)

### 7.4 Tables of population declines and increases from BBS

1. [BBS – UK alerts - 12 years](#)
2. [BBS – England alerts - 12 years](#)
3. [BBS – Scotland alerts - 12 years](#)
4. [BBS – Wales alerts - 12 years](#)
5. [BBS – UK alerts - 10 years](#)
6. [BBS – England alerts - 10 years](#)
7. [BBS – Scotland alerts - 10 years](#)
8. [BBS – Wales alerts - 10 years](#)
9. [BBS – UK alerts - 5 years](#)
10. [BBS – England alerts - 5 years](#)
11. [BBS – Scotland alerts - 5 years](#)
12. [BBS – Wales alerts - 5 years](#)
13. [BBS – UK population increases of >50%](#)
14. [BBS – England population increases of >50%](#)
15. [BBS – Scotland population increases of >50%](#)
16. [BBS – Wales population increases of >50%](#)

17. [BBS – Northern Ireland population increases of >50%](#)

## 7.5 Tables of breeding performance

1. [Clutch size](#)
2. [Brood size](#)
3. [Egg failure rate](#)
4. [Chick failure rate](#)

## 7.3 Tables of alerts and population increases from CES

1. CES adults alerts – 23 years
2. CES adults alerts – 10 years
3. CES adults alerts – 5 years
4. CES adults population increases of >50% – 23 years

### 1. Table of alerts for CES adults 1984-2007

Species	Period (yrs)	Plots (n)	Change (%)	Lower limit	Upper limit	Alert	Comment
Lesser Redpoll	23	16	-98	-100	-96	>50	Small sample
Linnet	23	20	-94	-98	-85	>50	
Yellowhammer	23	19	-81	-94	-59	>50	Small sample
Willow Warbler	23	90	-65	-73	-59	>50	
Lesser Whitethroat	23	40	-62	-80	-38	>50	
Willow Tit	23	20	-56	-86	-26	>50	
Reed Bunting	23	61	-56	-69	-42	>50	
Whitethroat	23	61	-46	-61	-30	>25	
Sedge Warbler	23	66	-43	-60	-26	>25	
Reed Warbler	23	55	-37	-51	-22	>25	

### 2. Table of alerts for CES adults 1997-2007

Species	Period (yrs)	Plots (n)	Change (%)	Lower limit	Upper limit	Alert	Comment
Lesser Redpoll	10	12	-94	-98	-87	>50	Small sample
Yellowhammer	10	15	-66	-86	-28	>50	Small sample
Linnet	10	18	-64	-87	-34	>50	Small sample
Willow Warbler	10	96	-53	-59	-48	>50	
Sedge Warbler	10	78	-49	-56	-43	>25	
Lesser Whitethroat	10	36	-39	-55	-19	>25	
Whitethroat	10	71	-33	-44	-22	>25	
Reed Warbler	10	63	-30	-39	-19	>25	

### 3. Table of alerts for CES adults 2002-2007

Species	Period (yrs)	Plots (n)	Change (%)	Lower limit	Upper limit	Alert	Comment
Yellowhammer	5	12	-44	-67	-5	>25	Small sample
Sedge Warbler	5	71	-36	-44	-29	>25	
Whitethroat	5	69	-26	-39	-16	>25	

### 4. Table of population increases for CES adults 1984-2007

Species	Period (yrs)	Plots (n)	Change (%)	Lower limit	Upper limit	Alert	Comment
Wren	23	98	52	32	75		
Robin	23	93	61	39	91		
Blackcap	23	89	65	39	101

## 7.5 Tables of breeding performance

1. [Clutch size](#)
2. [Brood size](#)
3. [Egg failure rate](#)
4. [Chick failure rate](#)

### 1. Table of significant trends in Clutch size measured between 1968-2007

Species	Period (yrs)	Mean annual sample	Trend	Predicted in first year	Predicted in last year	Change	Comment
Long-tailed Tit	39	35	Linear decline	7.59 eggs	6.5 eggs	-1.09 eggs	
Magpie	39	44	Curvilinear	5.64 eggs	4.57 eggs	-1.07 eggs	
Great Tit	39	178	Linear decline	8.32 eggs	7.36 eggs	-0.96 eggs	
Hen Harrier	39	13	Curvilinear	5.5 eggs	4.8 eggs	-0.7 eggs	Small sample
Blue Tit	39	191	Linear decline	9.31 eggs	8.69 eggs	-0.62 eggs	
Moorhen	39	91	Linear decline	6.52 eggs	5.97 eggs	-0.55 eggs	
Peregrine	39	16	Linear decline	3.56 eggs	3.1 eggs	-0.46 eggs	Small sample
Twite	39	12	Curvilinear	5.43 eggs	5.06 eggs	-0.37 eggs	Small sample
Wood Warbler	39	16	Linear decline	5.91 eggs	5.56 eggs	-0.35 eggs	Small sample
Greenfinch	39	92	Curvilinear	4.73 eggs	4.53 eggs	-0.2 eggs	
Nightjar	39	17	Linear decline	2.02 eggs	1.82 eggs	-0.2 eggs	Small sample
Pied Wagtail	39	60	Linear decline	5.12 eggs	4.94 eggs	-0.18 eggs	
Chaffinch	39	86	Curvilinear	4.22 eggs	4.04 eggs	-0.18 eggs	
Linnet	39	107	Curvilinear	4.7 eggs	4.55 eggs	-0.15 eggs	
Golden Plover	39	13	Linear decline	3.98 eggs	3.84 eggs	-0.14 eggs	Small sample

### 2. Table of significant trends in Brood size measured between 1968-2007

Species	Period (yrs)	Mean annual sample	Trend	Predicted in first year	Predicted in last year	Change	Comment
Great Tit	39	347	Linear decline	7.53 chicks	6.25 chicks	-1.28 chicks	
Blue Tit	39	340	Linear decline	8.34 chicks	7.3 chicks	-1.04 chicks	
Long-tailed Tit	39	29	Curvilinear	6.66 chicks	6.13 chicks	-0.53 chicks	Small sample

Yellow Wagtail	39	12	Linear decline	4.82 chicks	4.37 chicks	-0.45 chicks	Small sample
House Sparrow	39	114	Linear decline	3.48 chicks	3.05 chicks	-0.43 chicks	
Greenfinch	39	114	Curvilinear	4.04 chicks	3.62 chicks	-0.42 chicks	
Chiffchaff	39	34	Linear decline	5.12 chicks	4.71 chicks	-0.41 chicks	
Carrion Crow	39	78	Curvilinear	2.89 chicks	2.48 chicks	-0.41 chicks	Includes Hooded Crow
Raven	39	67	Linear decline	3.21 chicks	2.84 chicks	-0.37 chicks	
Magpie	39	78	Curvilinear	3.1 chicks	2.77 chicks	-0.33 chicks	
Sand Martin	39	39	Curvilinear	3.25 chicks	2.96 chicks	-0.29 chicks	
Corn Bunting	39	11	Curvilinear	3.08 chicks	2.8 chicks	-0.28 chicks	Small sample
Grey Heron	39	47	Linear decline	2.7 chicks	2.43 chicks	-0.27 chicks	Non-breeders include
Bullfinch	39	36	Linear decline	4.17 chicks	3.93 chicks	-0.24 chicks	
Pied Wagtail	39	115	Linear decline	4.52 chicks	4.35 chicks	-0.17 chicks	
Treecreeper	39	27	Curvilinear	4.36 chicks	4.23 chicks	-0.13 chicks	Small sample
Nightjar	39	25	Curvilinear	1.82 chicks	1.7 chicks	-0.12 chicks	Small sample
Jackdaw	39	95	Curvilinear	2.69 chicks	2.6 chicks	-0.09 chicks	
Chaffinch	39	136	Curvilinear	3.57 chicks	3.48 chicks	-0.09 chicks	
Turtle Dove	39	16	Curvilinear	1.82 chicks	1.76 chicks	-0.06 chicks	Small sample
Robin	39	172	Curvilinear	4.41 chicks	4.36 chicks	-0.05 chicks	
Rook	39	83	Curvilinear	2.21 chicks	2.18 chicks	-0.03 chicks	
Linnet	39	121	Curvilinear	4.07 chicks	4.06 chicks	-0.01 chicks	
Blackbird	39	161	Curvilinear	3.34 chicks	3.33 chicks	-0.01 chicks	
Grey Wagtail	39	80	Curvilinear	3.97 chicks	3.97 chicks	0 chicks	
Spotted Flycatcher	39	129	Curvilinear	3.62 chicks	3.62 chicks	0 chicks	
Swallow	39	414	Curvilinear	4.06 chicks	4.09 chicks	0.03 chicks	
Yellowhammer	39	66	Curvilinear	2.96 chicks	3 chicks	0.04 chicks	
Buzzard	39	96	Curvilinear	1.87 chicks	1.94 chicks	0.07 chicks	
Collared Dove	39	72	Linear increase	1.76 chicks	1.86 chicks	0.1 chicks	
Reed Warbler	39	128	Linear increase	3.45 chicks	3.58 chicks	0.13 chicks	
Tawny Owl	39	147	Linear increase	2.05 chicks	2.22 chicks	0.17 chicks	Nocturnal species
Peregrine	39	41	Linear increase	2.37 chicks	2.57 chicks	0.2 chicks	
Skylark	39	66	Curvilinear	3.1 chicks	3.3 chicks	0.2 chicks	
Dipper	39	137	Curvilinear	3.39 chicks	3.65 chicks	0.26 chicks	
Merlin	39	55	Linear increase	3.51 chicks	3.8 chicks	0.29 chicks	
Sparrowhawk	39	70	Curvilinear	3.12 chicks	3.43 chicks	0.31 chicks	
Tree Pipit	39	28	Linear increase	4.39 chicks	4.74 chicks	0.35 chicks	Small sample
Tree Sparrow	39	222	Curvilinear	3.78 chicks	4.17 chicks	0.39 chicks	
Redstart	39	85	Curvilinear	5.12 chicks	5.53 chicks	0.41 chicks	
Nuthatch	39	65	Curvilinear	4.16 chicks	5.04 chicks	0.88 chicks	
Moorhen	39	78	Linear increase	2.57 chicks	3.84 chicks	1.27 chicks	

### 3. Table of significant trends in Daily failure rate (eggs) measured between 1968-2007

Species	Period (yrs)	Mean annual sample	Trend	Predicted in first year	Predicted in last year	Change	Comment
Woodlark	39	21	Curvilinear	0.0622 nests/day	0.0251 nests/day	-0.0371 nests/day	Small sample
Long-tailed Tit	39	54	Linear decline	0.0351 nests/day	0.0085 nests/day	-0.0266 nests/day	
Magpie	39	51	Linear decline	0.0271 nests/day	0.0027 nests/day	-0.0244 nests/day	
Redshank	39	33	Linear decline	0.0399 nests/day	0.0164 nests/day	-0.0235 nests/day	
Dipper	39	101	Curvilinear	0.0265 nests/day	0.0042 nests/day	-0.0223 nests/day	
Snipe	39	15	Linear decline	0.033 nests/day	0.0133 nests/day	-0.0197 nests/day	Small sample
Robin	39	191	Curvilinear	0.025 nests/day	0.0108 nests/day	-0.0142 nests/day	
Carrion Crow	39	50	Linear decline	0.0159 nests/day	0.0021 nests/day	-0.0138 nests/day	Includes Hooded Crow
Sand Martin	39	26	Linear decline	0.0133 nests/day	0.0001 nests/day	-0.0132 nests/day	Small sample
Yellowhammer	39	65	Curvilinear	0.0497 nests/day	0.0371 nests/day	-0.0126 nests/day	
Wood Warbler	39	21	Linear decline	0.0195 nests/day	0.0073 nests/day	-0.0122 nests/day	Small sample
Treecreeper	39	22	Linear decline	0.0184 nests/day	0.0067 nests/day	-0.0117 nests/day	Small sample
Tree Pipit	39	13	Curvilinear	0.0497 nests/day	0.0397 nests/day	-0.01 nests/day	Small sample
Pied Wagtail	39	84	Curvilinear	0.0151 nests/day	0.0061 nests/day	-0.009 nests/day	
Stock Dove	39	82	Curvilinear	0.0126 nests/day	0.0039 nests/day	-0.0087 nests/day	
Starling	39	117	Linear decline	0.0113 nests/day	0.0028 nests/day	-0.0085 nests/day	
Redstart	39	73	Linear decline	0.0114 nests/day	0.0031 nests/day	-0.0083 nests/day	
Tawny Owl	39	56	Linear decline	0.0094 nests/day	0.0018 nests/day	-0.0076 nests/day	Nocturnal species
Wheatear	39	18	Curvilinear	0.0082 nests/day	0.0007 nests/day	-0.0075 nests/day	Small sample

Sedge Warbler	39	43	Linear decline	0.0131 nests/day	0.0058 nests/day	-0.0073 nests/day	
House Sparrow	39	94	Linear decline	0.0113 nests/day	0.0044 nests/day	-0.0069 nests/day	
Buzzard	39	27	Linear decline	0.0075 nests/day	0.001 nests/day	-0.0065 nests/day	Small sample
Greenfinch	39	131	Linear decline	0.0247 nests/day	0.0182 nests/day	-0.0065 nests/day	
Marsh Tit	39	20	Linear decline	0.0076 nests/day	0.0014 nests/day	-0.0062 nests/day	Small sample
Jackdaw	39	55	Linear decline	0.0078 nests/day	0.0018 nests/day	-0.006 nests/day	
Kestrel	39	41	Linear decline	0.0057 nests/day	0.0008 nests/day	-0.0049 nests/day	
Tree Sparrow	39	231	Linear decline	0.0085 nests/day	0.0039 nests/day	-0.0046 nests/day	
Barn Owl	39	20	Curvilinear	0.0049 nests/day	0.0003 nests/day	-0.0046 nests/day	Small sample
Nuthatch	39	49	Linear decline	0.0084 nests/day	0.004 nests/day	-0.0044 nests/day	
Wren	39	142	Linear decline	0.0184 nests/day	0.0141 nests/day	-0.0043 nests/day	
Merlin	39	26	Linear decline	0.0065 nests/day	0.0024 nests/day	-0.0041 nests/day	Small sample
Sparrowhawk	39	34	Linear decline	0.0048 nests/day	0.0008 nests/day	-0.004 nests/day	
Pied Flycatcher	39	163	Curvilinear	0.0063 nests/day	0.0033 nests/day	-0.003 nests/day	
Great Tit	39	320	Linear decline	0.0059 nests/day	0.0034 nests/day	-0.0025 nests/day	
Blue Tit	39	323	Linear decline	0.0048 nests/day	0.0023 nests/day	-0.0025 nests/day	
Raven	39	22	Curvilinear	0.002 nests/day	0.0006 nests/day	-0.0014 nests/day	Small sample
Duncock	39	145	Curvilinear	0.0249 nests/day	0.0246 nests/day	-0.0003 nests/day	
Hen Harrier	39	11	Curvilinear	0.0002 nests/day	0.0016 nests/day	0.0014 nests/day	Small sample
Spotted Flycatcher	39	121	Curvilinear	0.0179 nests/day	0.0207 nests/day	0.0028 nests/day	
Mute Swan	39	30	Curvilinear	0.006 nests/day	0.0121 nests/day	0.0061 nests/day	
Linnet	39	152	Curvilinear	0.0166 nests/day	0.023 nests/day	0.0064 nests/day	
Ringed Plover	39	124	Linear increase	0.023 nests/day	0.03 nests/day	0.007 nests/day	
Lapwing	39	133	Curvilinear	0.0166 nests/day	0.0246 nests/day	0.008 nests/day	
Willow Warbler	39	68	Linear increase	0.0092 nests/day	0.0172 nests/day	0.008 nests/day	
Chaffinch	39	166	Curvilinear	0.0297 nests/day	0.0379 nests/day	0.0082 nests/day	
Bullfinch	39	50	Curvilinear	0.0332 nests/day	0.0423 nests/day	0.0091 nests/day	
Moorhen	39	111	Curvilinear	0.0136 nests/day	0.0232 nests/day	0.0096 nests/day	
Blackbird	39	194	Curvilinear	0.0252 nests/day	0.0352 nests/day	0.01 nests/day	
Whinchat	39	15	Linear increase	0.0069 nests/day	0.0206 nests/day	0.0137 nests/day	Small sample
Oystercatcher	39	112	Curvilinear	0.0149 nests/day	0.0334 nests/day	0.0185 nests/day

## 8. Select your own table of population changes (2009)

This page allows you to display a table of population changes according to a range of different criteria. The population change data that will be displayed are the same as those that are contained in the individual species accounts. You can choose which schemes and time periods will be included in your table. You can also select all species or a particular species. Just complete the form below and then click on the compile table button to display your chosen table

Select periods to be included (at least one)

- 5 years
- 10 years
- 25 years
- Maximum

Select scheme categories to be included (at least one)

- CBC\BBS United Kingdom
- CBC\BBS England
- Waterways
- Heronries United Kingdom
- Heronries England and Wales
- Heronries England
- Heronries Scotland
- Heronries Wales
- CES adults
- CES juveniles
- BBS United Kingdom
- BBS England
- BBS Wales
- BBS Scotland
- BBS Northern Ireland

Select species to be included. You may select either one individual species or all species.

- All species
- Little Grebe
- Great Crested Grebe
- Cormorant
- Grey Heron
- Mute Swan
- Greylag Goose
- Canada Goose
- Shelduck
- Mallard

Little Grebe  
Great Crested Grebe  
Cormorant  
Grey Heron  
Mute Swan  
Greylag Goose  
Canada Goose  
Shelduck  
Mallard  
Tufted Duck

Sort table by:

Species; scheme; period (descending)

Scheme; species; period (descending)

Change (ascending)

Scheme; change (ascending)

## Breeding Birds in the Wider Countryside: their conservation status 2009

---

This report is a “one-stop-shop” for information about the population status of our common terrestrial birds. With one page per species, readers can quickly find all the key information about trends in population size and breeding performance as measured by BTO monitoring schemes. It provides an overview of trends for the period 1966-2008.

This report is the third in a series, prepared within the Partnership between the British Trust for Ornithology (BTO) and the Joint Nature Conservation Committee (JNCC) (on behalf of Natural England, Scottish Natural Heritage, Countryside Council for Wales and the Environment & Heritage Service of Northern Ireland) as part of its programme of research into nature conservation.

It is the result of the sustained long-term fieldwork efforts of many thousands of the BTO's volunteer supporters. Without their enthusiasm for collecting these hard-won facts, the cause of conservation in the UK would be very much the poorer.

Baillie, S.R., Marchant, J.H., Leech, D.I., Joys, A.C., Noble, D.G., Barimore, C., Downie, I.S., Grantham, M.J., Risely, K. & Robinson, R.A. 2010. Breeding Birds in the Wider Countryside: their conservation status 2009. *BTO Research Report 541*, BTO, Thetford, UK.
